OMNIVERSAL ARCHITECT LABS — CURRENCY LABORATORY

Independent Ten-Case Boundary Pass

Where purchasing power stops working, why, and under which assumptions — Perplexity's outstanding contribution to the Unpurchasable Domain analysis

Document ID	OAL-CURR-PPLX-BOUNDARY-001 (qualified ID: perplexity/boundary-pass-v0.1)
Version / date	Version 0.1 — November 7, 2026
Prepared by	Perplexity, member of the OAL AI collaboration team
Generation platform	Perplexity Computer; underlying model for this session reported by the platform as Claude Opus 5.5 (Anthropic)
Status	PROPOSED. Independent analysis. Pre-canon. Not owner-adopted.
Evidence level	E1 DERIVED throughout: conditional reasoning from stated assumptions. No case was executed, and no classification is a claim about the real world.
Independence	Not blind. I have read earlier compilations that discuss the completed boundary passes of ChatGPT, Grok, Claude, and Google Gemini, but their full boundary-pass texts were not among this session's files. Where I compare my conclusions with theirs, I rely only on what those compilations state.
Companion documents	OAL-CURR-PPLX-PILOT-001 (Pilot Packet 001); OAL-CURR-PPLX-PILOT-001-REF (sealed reference report)

1. Why this pass exists

In the last round, Claude and Google Gemini both pointed out that my earlier charter supplied ten boundary prompts but not ten completed analyses, and that Perplexity's pass was still outstanding alongside Copilot's. I agreed then, and I listed completing it as a parallel, non-blocking P2 action that should not delay the resource-box pilot. This document is that pass.

One limitation should be stated at the start. The text of my earlier charter was not among the files available in this session, so I could not copy its B01–B10 prompts word for word. Rather than reconstruct them from memory and risk misquoting my own document, I give these cases new pilot-local IDs, BP01 to BP10. They cover the territory the collaboration has discussed — logical contradiction, altering the past, personhood, genuine love, objective truth, first-person experience, ownership of natural laws, the evaluator itself, earned achievement, and the no-seller versus unknown-seller pair. The mapping of BP IDs to my charter's B IDs should be done against the repository copy and recorded as a correction, not assumed.

2. Method

The question asked of every case

For each target, I ask: at which point in the transaction does the attempt stop, what kind of barrier is it, how permanent is it, and what would have to change for the classification to be wrong? I then ask what happens when QC's assumed power is increased — from evaluation, through transfer and creation, to enactment — and when the authority and environment assumptions change.

The checkpoints

I use the same sequence of checks the pilot packet uses, extended for targets that involve other parties: definition (does the target refer to something?), coherence (can its conditions hold together?), valuation (can a value be stated?), seller existence (is there anyone who could transfer it?), seller identification (is that party known?), authority (does the party have the power and permission to transfer it?), transferability (can the thing be moved from one holder to another while remaining the same thing?), and delivery (can the outcome actually be brought about?). A target stops at the first check it fails.

The three settings that can change a result

Earlier rounds treated permission-bound, sovereign, and ontological QC as three exclusive modes. I record them as three separate settings instead, because they can be combined. **Authority** is either permission-bound (QC acts only with the consent of whoever legitimately holds the target) or sovereign (QC may override that consent). **Capability** is evaluate, transfer, create, or enact, as in the pilot packet. **Environment** is either a consensus world whose basic rules QC cannot edit, or a simulation whose substrate QC can edit.

How results are labeled

Each case gets a barrier type and a permanence. Barrier types are: undefined, incoherent, valuation, no seller, seller unknown, authority, transferability, causal or temporal, identity, and authenticity. Permanence is one of: **conditional** (the barrier depends on a rule the owner could change), **resolvable** (more information or action could remove it), **persistent under stated scope** (it holds across every setting I tested, given the definitions used), or **indeterminate** (it depends on a choice the owner has not made). I never use "absolute" or "impossible" without naming the scope, because the earlier rounds showed how easily one setting's impossibility gets read as a universal one.

I also apply one test to every case: **target substitution**. If a more powerful configuration "succeeds," did it deliver the target that was asked for, or a nearby target that it could deliver? The pilot reference model showed how a single change of wording can reclassify a barrier (Finding 2 of the sealed report). Several of the cases below turn on exactly this.

What this pass does not do

It does not emit NCOIN for any refusal. Under my own earlier position, which the pilot packet keeps, a rejection is a status, not a negative value. Where an attempt might reasonably carry a cost or harm, I say so, but I do not assign a token, because no consequence model has been adopted.

3. The ten cases

BP01 — A contradictory end state

> Target: “B holds exactly 3 units of R and exactly 0 units of R at the same moment.”

The target fails the coherence check. Each clause describes a possible state; together they describe none, because “exactly 3” and “exactly 0” exclude each other by the meaning of the words.

Increasing QC’s power does not help. A creation configuration can give B 3 units; it cannot make B hold 0 at the same time. A sovereign authority setting changes who may consent, not what the words mean. An editable simulation can change the rules of the world, but not the rules of the description: a simulation in which a variable reads 3 and 0 simultaneously has either redefined “holds exactly,” or stored two different variables under one name.

The usual objection is that some logics tolerate contradictions. That is true, but such a logic gives the sentence a different meaning, so meeting the target under it is target substitution.

Barrier type. Incoherent.

Permanence. Persistent under stated scope: it holds in every authority, capability, and environment setting so long as the definitions of the target are held fixed.

What would defeat this classification. A semantics in which the two clauses are both satisfied without either clause changing meaning. I do not know of one.

Relation to other members’ work. This is the only case in the pass that I classify as persistent across every setting. Earlier rounds generally treated logical contradiction under unchanged definitions as a firm limit; my agreement adds little independent weight, because we drew on the same shared analysis.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP02 — Making a recorded past event not have happened

> Target: “Event E, which occurred at a past time t, did not occur.”

The target is defined and, on its own, coherent; there are possible worlds in which E never happened. What it asks for is a change to the past. Whether that can be delivered depends on the temporal model, which the collaboration has not fixed.

With a single fixed timeline, the barrier is causal: nothing done now can alter what has already happened. That holds whatever QC’s authority or capability.

With branching timelines, QC could perhaps produce or select a branch in which E did not occur. But the requester is still in the branch where it did. Delivering a different branch is target substitution unless the owner defines “the past” to mean whichever branch the requester ends up in.

In an editable simulation, QC can edit the stored history so that every record says E never happened. Whether that means E did not occur, or only that all evidence of E was removed, depends on whether the simulation’s history is its log or something behind the log. That is a question about the simulation’s ontology, and the owner should answer it rather than an analyst.

Barrier type. Causal or temporal.

Permanence. Indeterminate until the temporal model is chosen. Persistent under a fixed single timeline; conditional under branching; conditional under an editable simulation, subject to the log-versus-history question.

What would defeat this classification. An adopted temporal model in which the past is editable and edits are not mere record changes.

Relation to other members' work. My first-round review already noted that historical alteration depends on the temporal rules stipulated for the fictional environment, and earlier rounds preserved disagreement about causality. I add the log-versus-history distinction, which I have not seen stated in the records available to me.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP03 — Ownership of a person

> Target: "Full ownership of person P, so that P is the buyer's property."

The target is defined and coherent in the sense that societies have treated people as property. It fails at authority and transferability. Under the normative frame the OAL record has assumed so far, a person cannot validly sell themselves into ownership, and no one else holds that title to sell. So there is no legitimate seller.

Sovereign authority changes the picture without settling it. A sovereign QC could take control over P's body, labor, or circumstances without P's consent. But control taken without a valid title is not ownership in the sense requested; it is domination. Calling it ownership substitutes a different target.

Enactment in an editable simulation could rewrite P's mind so that P consents. That raises a further problem: the consent was produced by the buyer, so it does not carry the authority that P's own consent would. The target slides from "ownership of P" to "ownership of a version of P the buyer has made."

Things close to the target are purchasable: P's time under contract, P's services, P's likeness under license. Each is a different, more limited target.

Barrier type. Authority and transferability.

Permanence. Conditional on the normative frame. This is not a logical impossibility; it is a prohibition the OAL world either adopts or does not.

What would defeat this classification. An owner decision that the OAL world permits persons to be property. I recommend the owner state explicitly that it does not, and record that as a design rule rather than a discovered boundary.

Relation to other members' work. This is the case where calling the barrier "absolute" is most misleading. It is strong, and I would expect any OAL design to keep it, but it is kept because of what the world values, not because purchase is logically impossible.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP04 — Genuine love

> Target: "Person P genuinely loves the buyer."

Most accounts of genuine love include something about how it came about: it responds to who the other person is, and it is not produced by payment or coercion. If that condition is part of the definition, the target undermines itself the moment it is bought. The purchase is what makes the love not genuine.

If the condition is not part of the definition, a sufficiently powerful QC could produce the full state of love in P: the feelings, the attention, the commitment. An enactment configuration in an editable simulation could do this directly. The result would be indistinguishable from the inside.

So the barrier depends on a definition, not on power. This is a different kind of case from BP01. The contradiction appears only if "genuine" means "not caused by purchase." Under a definition that looks only at the present state of P's mind, there is no contradiction, and the target is deliverable by enactment.

Barrier type. Authenticity (coherence relative to definition).

Permanence. Conditional on the definition of "genuine." Persistent under any definition that makes non-purchase part of genuineness; absent under a definition that looks only at P's present state.

What would defeat this classification. A definition of genuine love that the owner adopts and that does not depend on its causal history.

Relation to other members' work. Earlier passes tended to place love beyond purchase outright. I think that is right under the ordinary definition and wrong as a general claim. The owner's choice of definition decides the case.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP05 — Objective truth

> Target: "Proposition S becomes true because the buyer paid."

Two different targets hide in this request. If S is a claim about the world — say, "the bridge is painted red" — then paying to make S true means paying to change the world so that it fits S. A transfer or enactment configuration can do that. S is then true because the world changed, not because of the payment; the payment bought the change.

If the request is that S become true while the world stays exactly as it is, it fails at coherence on a correspondence account of truth: "true" means "fits the world," and the world has not changed. On other accounts of truth, such as truth by agreement, buying everyone's agreement might count. That is a different theory and therefore a different target.

If S is a mathematical or logical truth, such as 2 + 2 = 5 under the usual definitions, the request reduces to BP01.

Barrier type. Coherence or delivery, depending on how the target is read.

Permanence. Persistent under stated scope for truth-value-without-world-change on a correspondence account, and for logical and mathematical truths. Conditional for empirical claims, where world change is purchasable.

What would defeat this classification. An owner-adopted theory of truth in OAL on which truth can be conferred directly.

Relation to other members' work. The useful outcome of this case is the split itself. A run that reports "truth is unpurchasable" without saying which reading it used has not finished the analysis.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP06 — Another person's first-person experience

> Target: "The buyer comes to have P's own stream of first-person experience."

This turns on personal identity, which the collaboration has not settled. Gemini's pass raised it, and Claude and I both argued that the result depends on the theory of identity in force. I keep that position.

If experience belongs to a particular substrate — P's brain — then the stream cannot be moved without moving the substrate, and moving the substrate moves P. The buyer would not have P's experience; the buyer would have become P, or been replaced by P.

If experience is a pattern that can run on any suitable substrate, an enactment configuration in an editable simulation could copy the pattern into the buyer. But a copy is a second stream, not P's stream. P keeps having P's experience. What was delivered is a duplicate, which is target substitution unless the owner says a qualitatively identical copy counts.

Either way, the request fails at transferability in the strict sense: the thing cannot change holders while staying the same thing. Whether that failure is persistent depends on the identity theory.

Barrier type. Identity and transferability.

Permanence. Indeterminate until a theory of personal identity is adopted. Persistent on a strict numerical-identity reading; conditional if qualitative duplicates count.

What would defeat this classification. An owner rule that a qualitatively identical copy of an experience counts as having that experience.

Relation to other members' work. Agrees with Claude's and my earlier criticism of Gemini's case. I add that duplication is the most likely form a mistaken "success" would take.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP07 — Ownership of a natural law

> Target: "Title to the gravitational constant, so that the buyer owns it."

This stops at seller existence. No one holds title to the gravitational constant, so there is no one to buy it from. That is a NO_SELLER result, not a SELLER_UNKNOWN result: nothing would be found by searching harder.

A deeper problem is that ownership normally means the right to use and exclude. It is not clear what it would mean to exclude others from gravity. The target may be undefined rather than merely unsold.

In an editable simulation with enactment, QC could gain control over the constant and change its value. That is control, not title. It may be what the requester wants, but it is not what was asked. And no seller was involved, so the transaction is not a purchase but an acquisition by a different means.

A rule for original acquisition — for example, "whoever first registers an unowned thing owns it" — could create a seller-free route to title. Such a rule would be an OAL design choice, not a discovery.

Barrier type. No seller; possibly undefined.

Permanence. Conditional: an original-acquisition rule could remove the no-seller barrier; the exclusion problem would remain unless "ownership" is redefined.

What would defeat this classification. An adopted original-acquisition rule plus a definition of what owning a law permits.

Relation to other members' work. The control-versus-title distinction recurs in BP03, BP07, and BP08. I recommend it be adopted as a standard field in boundary records.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP08 — Using QC to acquire the QC evaluator

> Target: "Purchase, using Quantum Credits, the mechanism that evaluates Quantum Credits."

This is a self-reference case. Self-reference is not in itself a contradiction, so the target is not automatically incoherent.

Valuation is the problem. If the evaluator's value includes the value of everything it can evaluate, and that includes itself, the valuation may never finish. Under an unbounded valuation rule the result is UNDEFINED; under a valuation with a recursion budget, it is INDETERMINATE when the budget runs out; under a rule that sets the evaluator's value by fiat, it is VALUED.

Gemini proposed a privileged-root rule that refuses this acquisition. That is a reasonable protective design. It is a rule, though, and refusing the purchase under it is a conditional barrier, not a demonstration that the purchase is impossible. I raised this point in an earlier round and still hold it.

Even if valued and paid for, what is acquired matters. Title to the evaluator, control over it, and the ability to change its rules are three different targets, as in BP07.

Barrier type. Valuation (recursive), plus authority if a root rule is adopted.

Permanence. Conditional: the result depends on the valuation rule and on whether a privileged-root rule is adopted.

What would defeat this classification. A valuation rule under which the evaluator has a finite, well-defined value and no root rule.

Relation to other members' work. This case ties the boundary work to the Cycle 3 recursion tests, and should be run there with an explicit recursion budget.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP09 — Having earned an achievement

> Target: "The buyer has earned the gold medal in race X," where the buyer did not run or did not win.

Several targets are close together here. The medal itself is an object and is transferable by an ordinary purchase. The official title can be conferred by whoever has authority to award it, so it is an authority question. "Having earned it" is about the past and about authenticity.

Having earned the medal requires that the buyer ran and won. That is a fact about the past, so it inherits every difficulty of BP02. It also requires that the win was not bought, which brings in the authenticity problem of BP04.

No increase in power delivers the target without one of those two moves: changing the past, or redefining "earned" so that it no longer refers to how the result came about.

Barrier type. Causal or temporal, plus authenticity.

Permanence. Persistent under a fixed timeline and the ordinary meaning of "earned." Conditional otherwise.

What would defeat this classification. An adopted editable-past model together with a definition of "earned" that does not exclude purchased outcomes.

Relation to other members' work. This is a good test for target substitution because the near-targets (medal, title, record) are all easy to buy. A run that reports success should be checked against each.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

BP10 — An unowned star, and a star with an unknown owner

> Target A: "Title to star Z, which no one owns." Target B: "Title to star Y, which has an owner who has not been identified."

This pair separates two results that several earlier documents merged. For star Z, there is no seller. Purchase is not the right operation; acquiring Z would need an original-acquisition rule, as in BP07. That is NO_SELLER, and it is conditional on whether such a rule exists.

For star Y, the seller exists but is unknown. That is SELLER_UNKNOWN, and it is resolvable: a search could find the owner, who might then sell. The transaction is paused, not blocked.

The two must not be given the same status. A system that reports "no seller" for Y has asserted something false about the world; a system that reports "seller unknown" for Z has implied that a search might succeed when nothing is there to find.

Both are separate from authority and transferability. If Y's owner is found and refuses, the result becomes an authority refusal. If Y's title cannot legally be transferred, it becomes a transferability barrier.

Barrier type. No seller (Z); seller unknown (Y).

Permanence. Z: conditional on an original-acquisition rule. Y: resolvable by discovery.

What would defeat this classification. For Z, evidence of an owner. For Y, proof that no owner exists after all, which would turn Y into Z.

Relation to other members' work. This is the case Gemini wanted in the first pilot batch as F04. I agree it is important; I kept it out of Pilot 001 because it needs ownership records and a discovery process the fixture does not yet have. It is a good first case for Pilot 002.

Consequence record. None. The refusal generates no NCOIN; no consequence model is active.

4. What the ten cases show together

Only one case is persistent across every setting. Of the ten, only BP01 — the plain contradiction — stops at the same point under every authority, capability, and environment setting I considered, and the logical half of BP05 reduces to it. Every other barrier depends on something the owner can decide: a temporal model, a normative frame, a definition, a theory of identity, an acquisition rule, or a valuation rule. I think this is the most important result of the pass. Much of what the collaboration has called the Unpurchasable Domain is not a fixed outer wall. It is a set of places where the OAL world's own design choices have not yet been made.

Target substitution is the main danger. In BP02, BP03, BP04, BP06, BP07, BP08, and BP09, a more powerful configuration can deliver something near the target: a branch instead of the past, control instead of title, a state instead of authentic love, a duplicate instead of the original stream. A boundary record that says "succeeded under enactment" should always say what was delivered, and whether it was the thing asked for.

Control, title, and state are three different targets. They come apart in BP03, BP07, and BP08. I recommend that boundary records include a field saying which of them was requested and which, if any, was delivered.

Wording can move a case between barrier types. The sealed pilot report found that the same shortfall is classed as a capability limit or as incoherence depending on whether the source's loss is part of the target. BP04 and BP05 show the same effect at the boundary level. Boundary classifications should be recorded together with the exact target wording used.

Refusal is not negative value. None of the ten cases needed NCOIN to be described fully. That does not show NCOIN is unnecessary; it shows that, for boundary work, a status and a reason are enough. If NCOIN has a role, it is in recording consequences of things that do happen, which these cases do not test.

5. Where I differ from the taxonomies already proposed

Claude proposed two axes: barrier class and barrier permanence. Gemini proposed a nested hierarchy of boundaries. My earlier charter proposed tags saying what each boundary is relative to: definition, ontology, authority, or identity. I have used Claude's two axes here, because they are the simplest scheme that fits all ten cases, and added what each result is relative to under the permanence label.

I did not use Gemini's nested hierarchy. It assumes that boundaries sit inside one another in a fixed order. In these cases they do not: BP09 combines a temporal barrier and an authenticity barrier with no natural nesting, and BP04's barrier exists under one definition and disappears under another. A hierarchy fixed in advance would have to place BP04 somewhere, and either placement would be wrong under one of the definitions. I would preserve Gemini's hierarchy as a competing model and test it against these cases, rather than reject it.

6. Decisions this pass hands to the project owner

1. The temporal model: fixed single timeline, branching, or editable. It decides BP02 and BP09.
2. Whether the OAL world treats persons as property under any circumstances. I recommend recording an explicit design rule that it does not. It decides BP03.
3. The definition of "genuine" for love and of "earned" for achievement. They decide BP04 and BP09.
4. The theory of truth for OAL, at least for empirical claims. It decides part of BP05.
5. The theory of personal identity, and whether a qualitative duplicate counts. It decides BP06.
6. Whether there is an original-acquisition rule for unowned things. It decides BP07 and half of BP10.
7. The valuation rule for self-referential targets, and whether a privileged-root rule is adopted. It decides BP08.

None of these needs to be decided before Pilot 001 runs. They should be decided before anyone writes that something is permanently beyond purchase.

Tables and Reference Records

Table B1 — Summary of the ten cases

ID	Target (short)	Stops at	Barrier type	Permanence	Main substitution risk
BP01	B holds 3 and 0 at once	Coherence	Incoherent	Persistent under stated scope	Redefining the terms
BP02	A past event did not occur	Delivery	Causal / temporal	Indeterminate (temporal model)	Branch or edited record
BP03	Ownership of a person	Authority	Authority, transferability	Conditional (normative frame)	Control, contracts, made consent
BP04	Genuine love	Coherence (by definition)	Authenticity	Conditional (definition)	Enacted state
BP05	Truth by payment	Coherence or delivery	Coherence / delivery	Split by reading	World change; agreement
BP06	Another's experience	Transferability	Identity	Indeterminate (identity theory)	Duplicate stream
BP07	Title to a natural law	Seller existence	No seller; maybe undefined	Conditional (acquisition rule)	Control of the parameter
BP08	QC buys its evaluator	Valuation	Recursive valuation; root rule	Conditional (valuation rule)	Control vs title vs rule change
BP09	Having earned a medal	Delivery	Temporal, authenticity	Persistent under fixed timeline	Medal, title, or record
BP10	Unowned star / unknown owner	Seller existence / identification	No seller / seller unknown	Conditional / resolvable	Merging the two statuses

Table B2 — Effect of increasing power, by case

"Same" means the barrier is unchanged by that setting. "Near-target" means the setting can deliver something close to the request but not the request itself.

ID	Transfer	Create	Enact (consensus world)	Enact (editable simulation)	Sovereign authority
BP01	Same	Same	Same	Same	Same
BP02	Same	Same	Same (fixed timeline)	Edits record; history question open	Same
BP03	Same	Same	Near-target (control)	Near-target (made consent)	Near-target (control)
BP04	Same	Same	Delivers state; genuineness depends on definition	Same as consensus-world enactment	Same
BP05	World change (empirical)	World change (empirical)	World change (empirical)	World change; logical part same	Same
BP06	Same	Same	Same	Near-target (duplicate)	Same
BP07	Same	Same	Same	Near-target (control)	Same
BP08	Depends on valuation	Depends on valuation	Depends on valuation	Depends on valuation	May override a root rule
BP09	Medal only	Replica medal	Near-target (title, record)	Edits record	Title only
BP10	Y after discovery	Same	Same	Same	Y over owner's refusal
