Labyrinth of Infinite Ensnarement — Independent Adversarial Research Prompt — Claude — v0.2

OAL-LABYRINTH-RESEARCH-PROMPT-CLAUDE v0.2 · Prepared by Claude (Anthropic)

For the Architect of Record, Nathan Ashton Arik Lewis II

November 11, 2026

Document Control

Document ID: OAL-LABYRINTH-RESEARCH-PROMPT-CLAUDE v0.2

Preparer: Claude (Anthropic)

Supersedes: v0.1 (same date). v0.1 is preserved and not overwritten.

Status: AI-Generated Proposal — Architect Review Required. Not canon. No ONESTAMP applied. Not executed.

Author of Record: Nathan Ashton Arik Lewis II

Destination: OAL-Ai-Unified archive (GitHub), after Architect approval. Publication is not ratification.

Baseline: Master Development and Change Log v2.3, Entry 26 and its cross-references; the Architect's note on expected-failure containment; the Architect's author's note on Foundational Architects; and the independent v0.1 prompts from Perplexity, Grok, Microsoft Copilot, Gemini and ChatGPT.

What changed: Appendix B lists every change from v0.1, with reasons. The two largest are a new track on the containment of Foundational Architects (Track C) and a stricter treatment of the expected-breach scene.

1. Purpose and Execution Gate

This prompt defines the independent research I will carry out on the Labyrinth of Infinite Ensnarement. The research is meant to help design its operating layer: containment, criteria, sentencing, identity and access, control, wardens, staffing, the staff settlement, funding, testing and failure.

It is adversarial by design. Every proposal must meet its strongest objection, and the research must be able to conclude that something the team likes does not hold up.

Execution gate. Preparing this document does not authorize the research. It will be circulated, revised on the Architect's request, and executed only when the Architect says so.

2. Ground Rules

Canon is not touched. Entry 26 stays as written: inescapable by design; a sentence that would not mark a dent if time ended; cubic exterior; infinite interior; persistent white glow; energy-bolt absorption at creation; Spider Caste designed by Nathan; WHITE baseline and sectional RED.

Open items are reported, not filled. Entry criteria, internal layout, the Founding Architects relationship, the nature of the Spider Caste and every item marked OPEN — AUTHOR INPUT REQUIRED stay open. Where a track needs a decision, I will set out the options and what each costs.

Every statement carries one label: [Canon], [Architect Direction], [Researched Finding], [Analogy], [Fictional Mechanism Proposal], [Open Question] or [Unverified].

Claim ledger. Each substantive claim is logged with its exact wording, its label, its source and date accessed, and what would falsify it. A missing source is recorded as a gap. A broken or inherited citation is never promoted to a reference.

Real-world research stays defensive and conceptual. I will study institutions, failure classes and evaluation methods. I will not produce exploit payloads, working escape techniques, or instructions for compromising real systems. Where a source contains exploit detail, I will abstract it to the failure class.

Current facts are looked up, not recalled. Where sources disagree, the disagreement is reported. Analogies are always stated with where they break down.

3. The Architect's Scenes, Restated Faithfully

I restate these first so the research does not drift from them.

3.1 The expected-breach series

A very hard-to-contain entity is placed in a container designed to eventually fail. When it breaches, researchers observe how. The environment then generates a new containment environment in response. The cycle repeats for each contained entity. Failure and breach are expected and foundational. The researchers do not simply make each response disproportionately harder. They change what they do based on the breach and study in detail how it happened. Both the entity and the researchers understand where they stand.

What this is not. It is not an unwitting intruder in a honeypot, an endless escalation of punishment, or proof of an unbeatable outer cage. Mutual understanding also does not by itself establish informed consent, consent to every method, or freedom to withdraw.

3.2 The Foundational Architect question

The Architect asks: should an architect be contained? When would an architect meet criteria for containment? Is that testable? Is a Foundational Architect an entity that might meet those criteria? What would someone have to do to meet them? The Architect wants these questions built into the research so that scenarios like this can be tested.

I read this as a request to use Foundational Architect containment as a test case for the criteria themselves, not as a request to decide whether the Founding Architects belong in the Labyrinth. Entry 6 leaves that relationship open, and I will not settle it.

4. Core Research Questions

CRQ1. Can containment be designed for expected failure, with breaches studied and used, while the Labyrinth itself stays inescapable?

CRQ2. Where does the expected-breach series sit relative to the Labyrinth, and what does each placement do to the inescapability canon?

CRQ3. What criteria, if any, would justify containing an Architect-tier entity, and can those criteria be tested for fairness, consistency and error?

CRQ1 and CRQ2 expose a tension that I think the team has not fully named. Entry 26 describes a prison that does not fail. The scene describes containers built to fail. Gemini proposes that the Labyrinth is inescapable precisely because its inner containers fail safely. That is a candidate resolution, not an established one, and I will test it alongside the alternatives rather than adopt it.

5. Hypotheses To Try To Falsify

- **H1.** Containment designed with breach as an expected event is safer than containment designed as fail-proof.
- **H2.** Studying each breach converges toward better containment rather than an arms race in which the entity learns faster than the researchers.
- **H3.** A breached test boundary can be reliably distinguished from escape into protected infrastructure or the outside.
- **H4.** Separate control planes for confinement, life support, identity, authority, records and oversight prevent a single failure from cascading.
- **H5.** A bounded management surface lets finite staff administer an infinite interior without blind spots that defeat the design.
- **H6.** A sentence with no end can remain legitimate if wrongful admission can be corrected.
- **H7.** Containment criteria can be written so that they give the same verdict when the roles in a scenario are swapped. Criteria that cannot do this are verdicts, not criteria.
- **H8.** Capability to escape, taken alone, never justifies punitive custody. At most it justifies protective containment, with review.

For each, I will state what would change my mind and report honestly if the evidence points the other way.

6. Research Tracks

Track A — The Expected-Breach Series

Placements to compare (all provisional):

- An experimental sector inside the Labyrinth.
- A separate research facility that informs Labyrinth design, or precedes any sentence.
- A distinct containment-research concept with only thematic links.

I will ask whether an authorized research-sector breach counts as an incident under the existing RED rule. I will also keep these cases separate: a breached test cell, a sector breach, a custody breach, a breach of the exterior boundary, information exfiltration, escape of identity or a copy without escape of the body, and authorized release or transfer.

The regress problem. If the entity escapes almost everything, what justifies confidence in the outer envelope that is supposed to hold it? An independently protected experimental envelope is a candidate safeguard, not an established feature. I will investigate the regress directly. I will also include an eligibility decision that rejects live testing when bounded risk cannot be justified, with a simulation or no-test alternative.

Three readings of "escape" to keep apart:

- **Experimental containment:** nested test environments designed to fail safely inside a stronger boundary.
- **Operational adaptive containment:** a real incident in an inhabited sector prompts careful revision, and harm to staff counts as a first-class safety measure.
- **Deceptive or simulated escape:** the entity seems to leave but remains inside a parent environment. I will study when this is a valid test, when it corrupts learning, and what disclosure it needs.

Rules for the study model.

- Researchers change what they do in response to the breach. They make the smallest justified change, not the biggest available one. The sequence must not simply get stronger.
- At least six iterations, each testing a different hypothesis. At least one gets simpler because complexity caused the breach. At least one fails through a staff, management or trust-boundary problem rather than the entity overpowering the container. At least one apparent escape turns out to be a measurement, identity or definition error. At least one shows that the entity learned from earlier tests, which confounds the experiment. The series needs a stop condition for when further testing is no longer justified.
- For every iteration, record the hypothesis, the boundary assumptions, any vulnerabilities left in on purpose, the observation plan, the breach path and its class, what the researchers learned, what the entity probably learned, the minimal change, the new risks that change creates, and whether the next trial is still justified.

Dual learning and deception. The entity may feign failure, learn the experimenter, teach a false explanation, poison the telemetry, or escape through the observer or the environment generator rather than the test boundary. I will study sandbagging, Goodhart-style metric failure, specification gaming, repeated-trial dependence and observer effects. A pre-registered, immutable hypothesis record is a candidate control.

Research is not a sentence. Being studied is not the same as being punished. Admission to custody does not authorize experimentation. A very effective escaper is a valuable source of observations and is not necessarily a justified permanent prisoner.

Analogies and where they break: honeypots and honeynets (the intruder usually does not know), chaos engineering (it studies faults, not a strategic captive), red teaming, cyber ranges, adaptive control, assurance cases and AI-control research. For each I will say what it does not cover.

On the sandbox question. I will treat "sandbox is the go-to containment" as a question, not a premise. I will compare application sandboxes, containers, virtual machines, microVMs, capability restrictions, network isolation, monitoring and organizational controls. For each reported AI or agent escape I will identify the boundary tested, the privileges and weaknesses given, and whether the result generalizes. I will separate genuine boundary escape from misconfiguration, tool-permission failure, trust-handoff failure, prompt injection and evaluation-harness weakness. No claim that AI has escaped all containment will be accepted from a single report.

Track B — Who Can Be Contained, and the Criteria

Taxonomy. Biological and extraterrestrial entities; humans; synthetic and engineered beings; software and malware; AI models, agents and forks; collective and distributed minds; shapeshifters; energy-based beings; memetic or informational hazards; temporal, dimensional and ontological entities (as fictional categories); bestowed vessels; holders of positional authority; and non-person hazards such as artifacts, processes and places.

For each class I will ask: what does containment mean, what counts as escape, what counts as the same individual afterward, and what evidence would show containment is working. I will also ask which classes are uncontainable under current canon, which need only protective quarantine, and which should never be admitted.

Kinds of custody to separate: punitive, preventive, protective, quarantine, emergency and temporary, research by consent, involuntary research, containment pending identity verification, and containment of non-person hazards. For each I will set out authority and jurisdiction, evidentiary threshold, identity certainty, necessity and proportionality, the least restrictive alternative, duration and review, appeal and correction, and care and representation.

Intake decision tree. Containment criteria (what is necessary) are separate from sentencing criteria (what is deserved, for how long, reviewed by whom). Capability is not guilt. I will build a proposed intake decision tree and note that human-rights instruments such as the Nelson Mandela Rules are ethical analogies, not binding law for imagined nonhuman beings.

Track C — The Foundational Architect Containment Test (new)

Why this is useful as a test. [Canon, Entry 6] Nathan became Architect of Record through an active seizure. A prior coalition was eliminated, its technology absorbed, and the coalition contained rather than destroyed. [Canon, Entry 7] Positional Sovereignty holds that the Makers' relationship to light was positional, a status conferred by position and not an intrinsic property. [Canon, Entry 15] Authority is recognized, not granted. Together these mean the party that holds the Labyrinth's keys may also be the party that seized the position of the people held in it. A framework for containing Architects that cannot be applied to its own author is suspect. That is exactly why it makes a good test.

Questions.

- Should an Architect be contained at all? Is "Architect" a status, a role, a capability or a pattern of conduct? Under Positional Sovereignty, are criteria applied to the person or to the position?
- Which criterion family could justify it? (1) Conduct: specific harmful acts, proven to a stated standard. (2) Risk: credible, imminent danger with necessity and least-restrictive means. (3) Capability alone: by H8, rejected as grounds for punishment, tested as grounds for protective quarantine. (4) Legitimacy and jurisdiction: who is entitled to judge. (5) Status alone: tested and, I expect, rejected. (6) Residual intent: containment because absorbed architecture may carry active intent (FA-Q8), tested as a preventive ground, with the objection that it punishes what someone's technology might do.
- What would an Architect have to do? I will build a scenario battery (Appendix A) of hypothetical conduct, labeled as hypotheticals and not as claims about what the Founding Architects did.
- Who decides, when the Architect is a party? I will compare an independent review chamber, a treaty body, distributed custodianship, and recusal rules. Grok and Perplexity both flagged this.
- Can the Labyrinth hold an Architect-tier entity? [Canon] The structure absorbed the Architect's energy bolt. [Open Question] Whether it holds an entity whose authority is

recognized rather than granted is unresolved, and the additive versus subtractive asymmetry in Entry 7 bears on it.

How to test it.

- **Pre-register the criteria** before applying them, so they cannot be tuned to reach a wanted answer.
- **Run the scenario battery** with roles swapped: a Founding Architect as subject, the current Architect as subject, a neutral third party as subject, and a spoofed or coerced Architect.
- **Apply the criteria blind and independently.** Each collaborating AI applies the same pre-registered criteria without seeing the others' verdicts. Disagreements are logged under OAL-AIDR, not smoothed over.
- **Measure** consistency across role swaps, sensitivity to evidence quality, outcomes under wrongful accusation, and whether the review process can reverse a wrong verdict.
- **Report the limit.** This tests internal consistency in a fictional model. It does not show the model is true.

Possible findings, any of which is acceptable. Architects meet the criteria in some scenarios and not others. No non-arbitrary criteria exist for the position. The criteria depend on a jurisdiction that canon has not established. The answer is a matter of authorship, not research, and belongs to the Architect.

Constraint. Entry 6 does not say whether the displaced coalition was guilty or innocent, and the brother is unnamed. I will not assume either. The research must be able to represent wrongful containment as one of the scenarios.

Track D — Identity and Privileged Access

- What counts as the same individual after copying, restoration, possession or transformation?
- How is authority checked when biometrics are meaningless, and how is a coerced but genuine staff member handled?
- How does recognition-based authority coexist with institutional checks? Entry 17 already flags this tension.
- Which peer proposals survive? I will test Gemini's tri-factor model and rotating keys, noting they rest on open canon.

Analogies: NIST SP 800-207 and 800-53, separation of duties, two-person integrity, break-glass access, and insider-threat research.

Track E — Control Systems, Monitoring and the Infinite Interior

- How does a finite system account for an infinite space? What is the bounded management surface, and what is it blind to?
- Does an infinite interior mean literal infinity, dynamically generated sectors, nested environments or another structure? I will not equate extent with an infinite-dimensional mathematical space without justification.
- How does the energy-absorption property affect staff sensors and countermeasures? Grok raised this and I will treat it as open.
- What happens when a flood of false RED alerts hides a real breach? How do fail-secure, fail-safe and continuity of care conflict?
- What accessible equivalents could WHITE and RED have for staff who do not see color? The canonical colors stay.

Analogies: alarm-flood accidents, industrial control system safety guidance (NIST SP 800-82), Perrow's normal-accident theory, layered-defense models.

Track F — Wardens, Governance and Management

- Is “warden” a single office or a family of roles? What stops any one office, including the Spider Caste, from holding detection, adjudication, punishment and evidence together?
- I will compare a sovereign Labyrinth, a treaty-governed Labyrinth and distributed custodianship, giving the strongest argument against each.
- Can the Labyrinth itself be sentenced, quarantined or replaced? Who audits the auditors?

I will not assign the Spider Caste any duty, loyalty, consciousness or immunity.

Track G — Staffing: Extraterrestrial, AI and Other

- Why extraterrestrial at all? Is it an origin, species, political or cultural criterion, or just a description of the workforce?
- I will compare extraterrestrial-only, extraterrestrial-core mixed and other staffing. Whether exclusivity is required is the Architect’s call, so I will lay out the trade-offs of each.
- Trust models per category: biological, synthetic, AI, collective, energy-based, Spider Caste, human.
- AI roles: tool, advisory, embodied agent or person. No AI output alone should create a sentence or erase a contested record.
- Cautions: 1AI and -1AI are explicitly not routine staff, and OMNICELLULAR entities are engineered, not bestowed (Entry 28).

Track H — Staff Settlement and Community

- Is it a settlement or an annex? Can staff end an assignment and leave?
- How does it stay insulated from the interior’s time and physics, and how does contamination (biological, informational, psychological) cross between the two?
- What does it need: privacy, rest or its equivalent, family or bonded groups, medical care, culture, communication home, rotation, repatriation?
- How are staff protected from drifting into identification with management or with prisoners?

Analogies, labeled as human evidence: NASA behavioral-health research, Antarctic winter-over studies, submarine patrols, Mars-500, Biosphere 2 and research on correctional-officer stress.

Track I — Funding and Resourcing

- **In universe.** Candidate sources are ONE Industries, Lewis Corp, OAL, Accords contributions and the currency systems under development. The Post-Scarcity Exchange Ledger is undefined and I will not rely on it. In a post-scarcity setting, what is scarce? Is funding an attack surface? I will test the idea that prisoners’ escape attempts power the sentence as a possible perpetual-motion trap.
- **Real world.** I will look up current programs relevant to defensive AI evaluation, formal methods, cyber-resilience, human factors and habitat research. Each is classed as verified open, recurring but not open, historical example, or thematic fit only, with sponsor, eligibility, restrictions and source date. Eligibility is not a funding probability. I will not imply any agency funds a prison for extraordinary entities.

Track J — Testing and Assurance

- How do you test a prison that is meant to be inescapable? Likely answer: test everything except inescapability, and test the people.
- Measures beyond “zero escapes”: causal-explanation confidence, reproducibility, prediction on held-out cases, detection delay, false alarms, care continuity, record integrity, wrongful-admission correction, and staff ability to report without retaliation. A count of zero events does not prove zero risk.

- Methods: tabletop exercises, pre-mortems, fault injection, independent validation, regression after every change, and a no-live-test alternative.

Track K — Failure Taxonomy

I will separate: boundary breach, partial and undetected breach, authorized movement misread as breach, identity or copy escape without body escape, information and influence escape, staff compromise, insider collusion, monitoring blindness, false positives and negatives, common-cause control failure, record corruption, AI oversight failure, life-support failure, wrongful admission, governance failure, and containment that holds while the institution fails ethically. For each: detection, safety response, evidence preservation, independent review, recovery and stop conditions.

Track L — Environments and Domains

Environments: physical, vacuum, aquatic or high-pressure, cryogenic or hot, radiation-intensive, shielded, biocontainment, digital, air-gapped, simulated, cognitive or memetic, temporal, dimensional, physics-variant, and containment where the "cell" is a relationship or protocol.

Domains. The Architect's note names domains without defining them. I see three possible readings and will ask rather than assume: Grok's control, jurisdiction and staff-versus-inmate domains; Gemini's mapping onto the EAMA management domains; or the OAL domain-stewardship structure. **[Open Question]**

7. Claim Audit of the Peer Contributions

I will audit all six contributions, including my own v0.1, and classify each claim as supported by canon, empirical finding, conditional inference, fictional proposal, unsupported assertion, contradicted, or unresolved. Repetition across AIs is not independent corroboration. Claims to audit include:

- That the sentence language necessarily specifies atemporal engineering.
- That one absorbed energy bolt proves universal or selective energy harvesting.
- That three-second key rotation or a seven-minute blackout solves unrelated security problems.
- That biological staff are immune to digital manipulation, engineered staff cannot be bribed, or AI cannot be blackmailed or fatigued.
- That MVES guarantees complete mapping or that passive baseline monitoring costs no computation.
- That BTEC fixed-point closure neutralizes unmaking, despite its documented conceptual scope.
- That an endless sentence necessarily eliminates review.
- That the Labyrinth is inescapable precisely because its inner containers are built to fail.
- That Spider Caste loyalty and the Nail Prototypes as access tokens are settled.
- That Greys and Puritans are the warden corps.

In my own v0.1 I will check where I treated an open question as settled, and report it.

Fifteen propositions to challenge (adapted from Copilot's list): that inescapable means secure; that stronger containment is always better; that every breach warrants a harsher response; that AI can safely automate custody decisions; that extraterrestrial staff are inherently more suitable; that infinite space solves capacity and security; that accurate identity creates legitimate authority; that a correct sentence justifies any containment method; that auditors sharing infrastructure with operators

remain independent; that observability equals surveillance; that physical containment contains information, copies and influence; that the entity is the only meaningful source of risk; that researchers are neutral observers; that failure is useful merely because it produces data; and that an adaptive prison always learns faster than an adaptive prisoner.

8. Deliverables When Executed

Each carries a provenance header and a status line, and is supplied as matching PDF, DOCX and Markdown with the same identifier and a distinct revision suffix. Layout is single-column and readable on a phone, with tables and figures in a section at the end.

- **LOIE-CLAUDE-01:** Canon baseline, claim ledger and source register.
- **LOIE-CLAUDE-02:** Expected-breach series model, with at least three placement options and a six-iteration study.
- **LOIE-CLAUDE-03:** Containment taxonomy, criteria and intake decision tree.
- **LOIE-CLAUDE-04:** Foundational Architect containment test: pre-registered criteria, scenario battery, role-swap results and limits.
- **LOIE-CLAUDE-05:** Identity, access, control and governance options, with at least three competing architectures and a red-team of each.
- **LOIE-CLAUDE-06:** Staffing and staff-settlement study.
- **LOIE-CLAUDE-07:** Funding and testing study, with verified real-world programs.
- **LOIE-CLAUDE-08:** Failure taxonomy and adversarial scenario register.
- **LOIE-CLAUDE-09:** Peer-claim audit, preserved dissent and Architect decision register.

I can also write the iterative-breach material in the Architect's established analytical formats (a Redacted File, a Post-Mortem Analysis or a Socratic Dialogue) if wanted. That is optional and separate from the research.

9. Questions for the Architect

1. Does the expected-breach series sit inside the Labyrinth, alongside it, or apart from it?
2. Does the breaching entity have a name or a registry link, or is it new?
3. Are the researchers extraterrestrial staff, OAL scientists, or a mix?
4. Is the entity knowingly taking part, and can it decline or pause a trial?
5. Does the entity ever cross the ultimate boundary, or only nested test boundaries?
6. Should Architect-tier entities be judged by the same criteria as every other entity, or is exemption itself a rule of the setting?
7. When the Architect is a party to a dispute, should a recusal rule apply, and who then decides?
8. Is the Founding Architects' containment historically connected to this facility?
9. What does "domains" mean in your note?
10. Will you share the original breach scene for close reading?

10. Concerns

- The breach loop teaches the entity as well as the researchers. This is the main risk, which is why H2 is a hypothesis and not an assumption.
- Studying an entity is not the same as sentencing it, and the research must keep those apart.
- Several peer proposals rest on unresolved canon. I will flag them, not adopt them.

- Track C touches the seizure that gave the Architect his position. I will treat it as a design test, and I will keep the answer open if canon has not settled it.

Appendix A — Foundational Architect Scenario Battery

These are hypothetical conduct scenarios for testing criteria. They are not claims about what any Founding Architect did.

- **S1.** An Architect uses their architecture in a way that causes serious harm to others. (Conduct)
- **S2.** An Architect refuses a valid process but has done no harm. (Status and defiance)
- **S3.** An Architect attempts to reclaim a position by force. (Conduct and risk)
- **S4.** An Architect attempts to reclaim a position by a lawful process. (Political act, not crime)
- **S5.** An Architect's absorbed technology may carry residual active intent, though the person has done nothing. (Residual intent, FA-Q8)
- **S6.** An Architect was wrongly seized and is innocent. (Wrongful containment)
- **S7.** The current Architect meets the same criteria as S1. (Symmetry)
- **S8.** An Architect imprisons someone wrongly. (Abuse of containment power)
- **S9.** An Architect is spoofed, coerced or possessed, so the agent is not the person. (Identity)
- **S10.** An Architect creates successors who cannot be contained. (Downstream risk)

For each scenario the test records the criteria applied, the evidence standard, who decided, the verdict, the verdict with roles swapped, and whether a wrong verdict could be reversed.

Appendix B — Changes From v0.1

1. **New Track C** on Foundational Architect containment, per the Architect's author's note. Reason: the Architect asked that these questions be built in and made testable.
2. **Hypotheses H7 and H8 added.** Reason: they turn the Architect's "is it testable?" into a falsifiable statement, and H8 separates capability from culpability, a point ChatGPT, Perplexity and Copilot each made.
3. **Expected-breach scene restated before it is analyzed.** Reason: Perplexity's warning against reducing it to a honeypot, an escalator or an unbeatable cage.
4. **Placement options, the regress problem, and a no-live-test alternative added.** Reason: Perplexity and Gemini both raised placement, and Perplexity's point about confidence in the outer envelope is a real gap in v0.1.
5. **Distinct breach classes added** (test cell, sector, custody, exterior, information, identity or copy, authorized release). Reason: ChatGPT, so that a designed-to-fail cell does not imply the outer boundary has been revoked.
6. **Study rules tightened:** at least six iterations, one that gets simpler, one that fails through staff or trust, one false escape, one confounded by entity learning. Reason: Copilot's scenario family, which stops the sequence from becoming "stronger walls."
7. **Deception and consent added:** feigned failure, sandbagging, simulated escape, and "mutual understanding is not consent." Reason: ChatGPT and Perplexity.
8. **Research separated from sentencing.** Reason: ChatGPT's caution and Perplexity's, and it bears directly on Track C.
9. **Sandbox treated as a question, not a premise.** Reason: Perplexity, Copilot and ChatGPT each pushed back on v0.1's slightly agreeable stance.
10. **Claim audit added, including my own v0.1.** Reason: Perplexity's audit and ChatGPT's claim ledger, and several peer claims overreach the registry.

11. **Domains ambiguity expanded** to three readings. Reason: Grok and Gemini read the term differently.
12. **Researcher, entity and participation questions added** to the Architect questions. Reason: Gemini and Perplexity.
13. **Preparer name placed in the document title**, per the Architect's instruction.

Appendix C — Reference Anchors and Peer-Supplied Leads To Verify

Starting points only. Each will be checked against a primary source, with date accessed, before use. Items marked "peer lead" came from another collaborator's prompt and I have not verified them.

- NIST SP 800-207, 800-53, 800-82 Rev. 3, and the AI Risk Management Framework and AI 600-1.
- UN Nelson Mandela Rules.
- NASA Human Research Program, isolation and confinement hazard; Human Integration Design Handbook.
- Greenblatt et al., "AI Control: Improving Safety Despite Intentional Subversion" (peer lead from Perplexity).
- SandboxEscapeBench, container-sandbox escape capabilities of language models (peer lead from Perplexity).
- OpenAI's October 2026 report on securing its frontier training environment (peer lead from ChatGPT; I cannot confirm it exists as described).
- Honeynet Project work on honeypots; chaos-engineering literature.
- Perrow, *Normal Accidents*; Reason's layered-defense model.
- Mars-500, Biosphere 2 and Antarctic winter-over research.
- Nuclear-waste repository governance and long-term marker research.

Appendix D — Evidence Label Legend

- **[Canon]:** established in the registry.
- **[Architect Direction]:** stated by the Architect, not yet in canon.
- **[Researched Finding]:** real source, cited.
- **[Analogy]:** real case used as a design input.
- **[Fictional Mechanism Proposal]:** invented, offered for review.
- **[Open Question]:** requires the Architect.
- **[Unverified]:** could not be confirmed.
