OAL - Labyrinth of Infinite Ensnarement

Independent Adversarial Research Prompt - Prepared by Microsoft 365 Copilot

Document ID: OAL-LOIE-PROMPT-COPILOT-002

Version: 0.2

Date: November 11, 2026

Architect and Author of Record: Nathan Ashton Arik Lewis II

Preparer: Microsoft 365 Copilot

Status: Revised independent research prompt - pending cross-AI review - not executed - not canon

Archive: OAL-Ai-Unified

1. Revision Purpose

This v0.2 prompt supersedes Copilot v0.1 for future execution while preserving v0.1 as a historical artifact. It incorporates the Architect's new note that Foundational Architects should be used as a test class: should an architect be contained, when could an architect meet criteria, is that determination testable, and what conduct could justify containment or sentencing?

It also incorporates the strongest review controls found across the attached prompts prepared by Grok, Perplexity, Gemini, Claude, and ChatGPT: preserve open canon; distinguish containment from sentencing; separate designed-to-fail test boundaries from the ultimate boundary; audit unsupported integrations; protect staff from becoming de facto prisoners; and treat sandbox escape claims by actual failure class rather than headline.

2. Governing Baseline

Preserve Entry 26: ultimate prison; inescapable by design; cubic exterior; infinite interior; persistent white glow; energy-bolt absorption at creation; Spider Caste; WHITE baseline; sectional RED incidents. Entry criteria, layout, Spider Caste nature, and Founding Architect linkage remain open.

Do not silently install Paragon Cubes, Void Sentry Orb, Nail Prototypes, MVES, BTEC, the Abundance Set, Prompt Potence, or any other unfinished OAL system. Treat each as a candidate interface requiring evidence, compatibility analysis, approval, and red-team review.

3. Research Method

For every claim: identify provenance; distinguish canon, Architect direction, empirical evidence, analogy, proposal, inference, and unknown; use current authoritative or primary sources; find contrary evidence; state limitations; define a falsification test; and preserve unresolved decisions.

The research must not aim to prove the Labyrinth correct. It must be able to conclude that a preferred mechanism, sentence, staffing model, or test is unsupported, unsafe, illegitimate, or untestable.

4. Central Research Question

How should an infinite, multispecies, multi-entity containment institution be designed when selected experimental containers are expected to fail and generate learning, while the institution must still preserve legitimate authority, scientific validity, staff safety, ethical limits, continuity, and the canon of an inescapable ultimate prison?

5. Required Research Domains

5.1 Containable Subjects and Hazards

Develop a taxonomy covering biological persons, extraterrestrial entities, synthetic life, robots, AI models and agents, distributed and collective minds, copies and forks, transferred consciousness, energy or informational entities, artifacts, processes, environments, memetic hazards, and explicitly fictional temporal, dimensional, ontological, and narrative classes.

For every class define: identity, continuity, containment meaning, escape meaning, observation limits, care needs, staff compatibility, false-positive harm, and conditions making live testing inappropriate.

5.2 Admission, Containment, and Sentencing

Separate punitive sentencing, protective containment, quarantine, emergency custody, voluntary research participation, involuntary research observation, and custody of non-person hazards. Research authority, jurisdiction, evidence, necessity, proportionality, least-restrictive alternatives, duration, review, appeal, correction, transfer, release, care, and representation.

Capability is not guilt. Technical containability is not sentencing legitimacy.

5.3 Adaptive Containment Through Expected Failure

Model a series of containers intentionally expected to fail. Researchers and the entity understand the study. Each breach is observed, causally reconstructed, and used to design a different next test. The response must not default to harsher or disproportionately difficult confinement.

Require at least six iterations. One must become simpler because complexity caused failure. One must fail through staff, management, or trust-handoff error. One apparent escape must be a measurement or identity error. One must show that the entity learned from prior trials. Include stop conditions and a no-live-test alternative.

For every iteration record: hypothesis, boundary, instrumentation, known weakness, breach class, evidence integrity, researcher learning, entity learning, minimal modification, new risk, ethics review, and stop/continue decision.

5.4 AI Sandboxes and Trust Boundaries

Research whether sandboxing is the dominant AI-agent containment approach or one layer among VMs, microVMs, containers, capability restrictions, least privilege, segmentation, tool mediation, offline evaluation, and external monitoring.

Separate genuine boundary escape, container breakout, control-plane weakness, shared-kernel weakness, unsafe permissions, egress, credential exposure, prompt injection, persistence, trust-

handoff failure, and unsafe external consumption of sandbox-produced files. Abstract exploit details into defensive failure classes.

5.5 Identity and Privileged Access

Research zero trust, privileged-access management, separation of duties, just-in-time authority, revocation, coercion, insider threats, audit independence, and conflicts between recognized creator authority and delegated governance.

Test copies, restoration, body exchange, possession, shared minds, temporal displacement, memory alteration, and credentials inherited after death or restoration. Separate privileges for observation, research, maintenance, admission, adjudication, sentencing, transfer, release, life support, and emergency response.

5.6 Controls, Wardens, and Management

Compare centralized, distributed, federated, and hybrid control. Separate containment, identity, authority, habitat/life safety, evidence, monitoring, research generation, sentencing records, and independent review. Test common-mode failure, alarm flooding, degraded operation, succession, compromised authentic users, unavailable leadership, and offline fallback.

Preserve WHITE and RED. Any additional state is a proposal.

5.7 Extraterrestrial, AI, Spider Caste, Human, and Other Staff

Compare extraterrestrial-only, extraterrestrial-majority, and mixed staffing. Treat origin, embodiment, personhood, competence, consent, environmental compatibility, independence, accountability, and rights as separate axes. Do not assign the Spider Caste a role, consciousness, loyalty, or immunity by inference. Distinguish AI tools, advisers, embodied agents, and possible AI persons.

5.8 Staff Settlement

Treat the living area as a community and workplace. Research atmosphere, pressure, gravity, radiation, light, noise, nutrition, waste, medicine, rest, privacy, recreation, culture, communication home, families or bonded groups, disability access, quarantine, emergency refuge, leave, resignation, asylum, repatriation, and freedom to depart through authorized procedures. Staff must not become another captive population.

5.9 Environments and Domains

Research physical, vacuum, aquatic, pressure, thermal, radiation, electromagnetic, biological, cyber, offline, simulated, cognitive, sensor-rich, sensor-denied, temporal, dimensional, topological, physics-variant, mobile, distributed, social, and explicitly fictional ontological environments. For each identify suitable occupants, exclusions, dependencies, observability, staff hazards, failure modes, recovery, and test prerequisites.

5.10 Failure, Recovery, and Testing

Create failure classes for boundary breach, partial or undetected breach, authorized movement misclassification, copy or identity escape, information/influence escape, staff compromise, sensor deception, common-mode failure, provenance corruption, AI drift, life-support failure, habitat contamination, wrongful admission, jurisdiction failure, sentence corruption, cascade, and institutional failure despite physical containment.

Test components, interfaces, faults, breach drills, tabletop exercises, simulations, independent validation, regression, staff evacuation, wrongful-admission correction, unavailable leadership, degraded modes, and long-duration continuity. Metrics must include learning quality, detection,

consequence containment, staff safety, record integrity, reversibility, correction, auditability, care continuity, and new vulnerabilities, not only zero escapes.

5.11 Funding

Research current, verifiable funding analogies for safe defensive research in AI security, resilient computing, cyber ranges, formal methods, autonomous systems, extreme-environment habitation, human factors, digital twins, and disaster resilience. Record sponsor, program, status, eligibility, scope, restrictions, partnerships, dual-use concerns, and retrieval date. Do not imply funding exists for extraterrestrial prisons or coercive experimentation.

Separately propose an in-universe staged R&D model: exploratory research, simulation, prototype, independent evaluation, adversarial exercise, architecture candidate, and canon-review gate.

5.12 Ethics and Research Governance

Use correctional, human-rights, research-ethics, medical-independence, and inspection standards as ethical analogies, not automatic extraterrestrial law. Separate voluntary study, custodial observation, safety evaluation, and coercive experimentation. Ask when studying escape becomes invalid, abusive, or too dangerous to continue.

5.13 Infinite Interior and Logistics

Use topology, graph theory, distributed systems, addressing, observability, infinite-state systems, and formal verification as analogies. Ask how finite administrators manage unbounded space, define a section, locate occupants, prove absence of breach, move staff, retrieve entities, preserve addresses, and avoid substituting the word infinite for an operating model.

6. Foundational Architects as a Test Class - Architect Containment Inquiry

Do not presume a Foundational Architect is imprisoned, guilty, containable, or exempt. Use this category to test whether criteria apply consistently to foundational, creative, administrative, or reality-shaping authority.

Ask separately:

1. Can an architect be contained? A capability, identity, access, topology, and systems question.
2. Should an architect be contained? An evidence, authority, necessity, proportionality, legitimacy, rights, and sentencing question.

Extraordinary capability, authorship, ownership, knowledge, or status does not by itself prove culpability. Architect status must not automatically create immunity if neutral criteria are met.

6.1 Architect Taxonomy

Distinguish original Foundational Architects; successor architects; administrative architects; former or revoked architects; architects whose work retains residual intent; distributed, copied, restored, collective, or time-displaced architects; architects who are custodians, judges, owners, witnesses, victims, or beneficiaries; architects recognized by legacy systems; and title-only architects versus entities with actual root-level power.

6.2 Candidate Criteria to Test

Adversarially evaluate whether containment could be considered when independently reviewable evidence supports ongoing or imminent catastrophic harm; repeated misuse of foundational authority; unauthorized alteration or coercive control of inhabited realities; corruption of identity, evidence, sentencing, or governance; violent or deceptive reclamation through residual

intent or legacy access; creation of continuing uncontrollable harm; circumvention of oversight or succession; privileged compromise of containment; or a demonstrated failure of less restrictive alternatives.

These are hypotheses, not canon. Require jurisdiction, evidence standards, causal connection, responsibility, necessity, proportionality, alternatives, duration, review, and correction.

6.3 Testability and Evaluator Problem

Research historical/provenance review, bounded simulations, counterfactuals, privilege-revocation exercises, independent residual-intent audits, non-self-incriminating behavioral evaluation, creator-backdoor red teams, and tests of less restrictive controls.

An architect may have authored the test, possess root access, be recognized as creator, alter evidence, or manipulate success criteria. Another office administering the same architecture does not make the test independent. State what cannot be tested reliably.

6.4 Required Architect Scenarios

Analyze at least six scenarios:

3. Catastrophic capability with no proven harmful act.
4. Credible allegation of continuing large-scale harm with disputed evidence.
5. A former architect using residual intent or legacy access to reclaim control.
6. Catastrophic past harm but low present risk.
7. An architect essential to maintaining reality or the Labyrinth.
8. A Labyrinth contributor who may exploit creator recognition but voluntarily submits to evaluation.

For each, separately assess investigation, temporary restriction, research observation, protective containment, punitive sentencing, alternatives, or no confinement. Do not force imprisonment.

6.5 Governance and Conflict of Interest

Test recusal, independent adjudication, treaty authority, distributed custodianship, temporary emergency power, evidence independence, appeal, whether one architect may contain another, whether the Labyrinth may refuse an architect's order, whether the Architect of Record can be evaluated under the same criteria, and who audits the authority declaring an architect containable.

6.6 Adaptive-Breach Connection

Use a Foundational Architect as one candidate for the designed-to-fail study without declaring that identity canon. Test whether valid learning is possible when the subject may have created the architecture, understands the researcher's design language, or selectively reveals escape methods to train the system toward a hidden objective.

Stop if the subject can manipulate the generator, observers, provenance, or parent boundary so thoroughly that causal learning is not trustworthy. Shift to simulation, external review, or non-performance.

7. Mandatory Adversarial Propositions

Challenge claims that inescapability equals security; stronger is always better; every breach requires escalation; AI should automate custody judgments; ET staff are inherently superior; infinity solves capacity; valid identity creates legitimate authority; a sentence justifies every method; shared-infrastructure auditors are independent; the prison learns faster than the prisoner; surveillance equals observability; physical confinement contains information and

influence; the entity is the only risk; researchers are neutral; or failure is useful merely because it creates data.

8. Cross-AI Claim Audit

Audit all attached prompts. Preserve useful disagreement. Specifically test: Perplexity's custody and evidence discipline; Grok's topology and residual-intent concerns; Claude's management surface and falsification framing; ChatGPT's claim ledger, twelve-trial matrix, and containment-civilization model; Gemini's integrations, many of which are proposals rather than established mechanisms; and Copilot's control-plane, entity taxonomy, governance, and adaptive-arms-race concerns.

Flag unsupported claims such as universal energy harvesting from one absorbed bolt, zero-compute monitoring, guaranteed sensing, fixed-point physical neutralization outside BTEC's stated scope, unquestioned Spider Caste loyalty, automatic AI immunity to coercion, or use of unfinished currency and funding systems as if operational.

9. Required Execution Deliverables

Produce: executive summary; canon/provenance matrix; methodology; cross-AI claim audit; containable-entity taxonomy; admission/sentencing framework; Foundational Architect inquiry and scenario matrix; adaptive breach laboratory with at least six iterations; AI sandbox findings; identity/access options; control and governance candidates; staffing models; staff-settlement study; environment taxonomy; failure/recovery taxonomy; testing framework; verified funding landscape; ethics analysis; infinite-interior study; three incompatible architecture candidates and red-team reviews; experiments/tabletops; Architect decision register; evidence-to-design matrix; source register; GitHub plan; and a dedicated visual appendix for all substantial charts, tables, matrices, diagrams, and figures.

10. Open Architect Questions

- Is Foundational Architect a status, capability class, historical group, or all three?
- Is any Foundational Architect currently intended to be imprisoned, or is this strictly a framework test?
- Can an architect meet the same criteria as any entity, or require special jurisdiction and evidence?
- Can the Architect of Record or a successor be evaluated under the same framework, and by whom?
- Is the designed-to-fail sequence inside the Labyrinth, a precursor, adjacent, or separate?
- Does inescapable prohibit authorized release or only unauthorized departure?
- What is the Spider Caste?
- Is ET staffing exclusive, dominant, or one class among several?
- Is the Labyrinth conscious and capable of refusing an order?
- Which parts should remain unknowable?

11. Safety and Output Discipline

Keep cybersecurity content defensive and non-operational. Do not provide real exploit instructions, attack payloads, evasion procedures, or instructions to harm facilities. Abstract unsafe details to failure classes. Clearly label canon, evidence, analogy, proposal, inference, and open questions.

12. Change Log

v0.2 - November 11, 2026: Added Foundational Architect containment inquiry; can-versus-should distinction; architect taxonomy; candidate criteria; testability and evaluator problem; six mandatory architect scenarios; conflicts of interest; Architect-of-Record applicability; adaptive-breach stop rule; expanded cross-AI claim audit; updated title to include preparer; retained all v0.1 domains concerning environments, funding, testing, failures, staffing, habitation, sentencing, AI sandboxing, and visual appendix requirements.
