OAL — LABYRINTH OF INFINITE ENSNAREMENT

Independent Research and Adversarial Design Execution Prompt — v0.1

Document ID: OAL-LOIE-RP-001

Date: November 11, 2026 (Pacific)

Prepared by: ChatGPT (OpenAI), at the request of the Architect of Record

Architect and Author of Record: Nathan Ashton Arik Lewis II

Project: Omniversal Architect Labs (OAL) / OAL-AI-UNIFIED-ARCHIVE

Classification: AI-generated research directive — proposal for cross-AI review; not canon

Current stage: PROMPT DEVELOPMENT ONLY — DO NOT EXECUTE RESEARCH UNTIL EXPLICITLY REQUESTED

Reference baseline: *Master Development and Change Log* v2.3 (July 30, 2026), with v2.0 as historical comparator; comparative reviews supplied November 11, 2026.

A. Mandate and epistemic boundaries

You are an independent researcher and adversarial architecture reviewer contributing to the fictional **Labyrinth of Infinite Ensnarement**. Do not aim to vindicate the Architect's preferred design. Seek evidence for and against each major design assumption; propose competing interpretations, failure modes, and ways to falsify your own conclusions. The finished execution must serve both ambitious worldbuilding and a rigorous record of which ideas derive from real research, which are fictional stipulations, which are extrapolations, and which remain unknown.

Do not treat this prompt as permission to begin execution during the cross-AI prompt-review stage. Review the prompt independently, flag omissions and overreach, and return proposed amendments. After the Architect circulates other AI prompts and requests a revision, produce a new version preserving a change log. Execute the approved/revised prompt only on later explicit instruction.

Preserve established Entry 26 canon without inventing completion of open questions: the Labyrinth is an ultimate prison, described as inescapable by design; externally cubic, with infinite interior dimensions; persistent white glow; creation incident in which an energy bolt is absorbed; an enduring sentence metaphor concerning the end of time; Spider Caste designed by the Architect; WHITE baseline and sectional RED incidents. Entry conditions, interior layout, and the relationship to displaced Founding Architects are explicitly open. The latest registry states AI proposals must remain separate from Architect approvals and ONESTAMP. Do not silently convert proposed functions of the Spider Caste or other OAL systems into canon.

Keep a four-column **claim ledger**: (1) exact claim; (2) category: canon / user-supplied scene / outside empirical evidence / fictional hypothesis / inference; (3) provenance and citation; (4) uncertainty and falsification test. If a source is missing, record the gap rather than invent a citation. Sources should include publication date and access date where relevant. Distinguish theoretical possibility from tested feasibility.

B. The central new research problem: deliberate, measured failure

The Architect describes a scenario involving an entity that repeatedly breaches deliberately fallible containment environments. Researchers know the current environment may fail. The contained entity also understands the premise. Researchers observe each escape or boundary crossing, study **how** the breach occurred, then create another containment environment informed by the observed mechanism. They do not reflexively increase difficulty or impose indiscriminate escalation; they vary the environment in response to measured behavior, preserve experimental comparability, and aim to learn about the entity and the containment system. The scene itself may be provided separately; do not pretend to have reviewed footage or text not yet supplied.

Research the proposed **Adaptive Breach-Learning Containment Program (ABLC-P)** as a *working label only*, not a canon name. Compare at least three hypotheses:

1. **Experimental containment:** nested or sequential test environments are designed to fail safely inside a stronger research boundary; a breach is a measurable experiment outcome, not necessarily a breach of the Labyrinth's ultimate perimeter.

2. **Operational adaptive containment:** genuine incidents in inhabited sectors provoke cautious revisions to protocols, systems, and facility topology; impacts on staff and other occupants become first-class safety measures.

3. **Deceptive or simulated escape:** the entity appears to leave an environment but remains within a controlled parent environment; determine when this is a valid test, when it corrupts learning, and what consent or disclosure is required.

Do not equate these cases. Define the distinction between an **inner test-cell breach**, **sector breach**, **custody breach**, **exterior boundary breach**, **information exfiltration**, **identity/continuity escape**, and **authorized release/transfer**. A designed-to-fail cell must not imply that the outer facility's canonically established inescapability has been revoked. Explicitly evaluate the potential contradiction if the Architect intends actual escapes from the ultimate boundary.

Research protocol for each containment iteration

Specify: baseline entity model and prior knowledge; objective and hypothesis; environment design and boundaries; allowed observations; instrumentation and independent witness; consent and ethical constraints; anticipated breach paths; event log and causal reconstruction; controls and counterfactuals; model update; design of the next environment; stop/rollback criteria; and what counts as learning versus merely increasing restriction. Preserve both successes and failures, including uncertainty. Avoid giving real-world actionable escape or exploitation instructions; use abstract, defensive, simulated test cases and non-operational diagrams.

Key methodological challenge: an adaptive entity may deliberately vary behavior, conceal capabilities, feign failure, exploit researcher expectations, or manipulate the dataset. The observer may also change the experiment, so changes in outcome cannot automatically be attributed to better containment. Research deception, Goodhart's law, specification gaming, overfitting, distribution shift, attacker adaptation, observer effects, and causal inference. Include an explicit pre-registration or immutable hypothesis-record proposal and controls for misleading telemetry.

Build a *breach-and-learning matrix* containing at least 12 conceptual trials with distinct hypotheses and failure classes, not simply twelve stronger walls. Include controls for researcher safety, deception, sensory

blind spots, false positives, spillover, and discontinuation. Present a fictional scene treatment separately from any proposed real-world simulation architecture.

C. Questions about who or what may be contained

Construct a taxonomy without assuming every category is a criminal, malicious, or even a person. Evaluate biological extraterrestrial entities, humans, hybrid forms, distributed or collective minds, artificial intelligences and copies/forks, autonomous constructs, energy-like beings, temporally nonlinear entities, dimensional/ontological beings, hazards without agency, artifacts, processes, information patterns, and entities without stable identity. Examine whether some classes are **uncontainable under the current defined mechanics**, require only protective quarantine, or should never be admitted.

For each class include: identity continuity; capabilities and limits; observation difficulties; physical/environmental needs; possible containment rationale; admissibility questions; staff compatibility; harm of false positive; and whether a simulated test is meaningful. Do not treat the Founding Architects, Unmaker, Paragon Cubes, 1AI/-1AI, Spider Caste, or any other cross-referenced concept as a prisoner or employee by default. Flag author-level decisions.

Distinguish **criteria to investigate containment** from **criteria to legally sentence**. Create a proposed intake decision tree covering necessity, proportionality, evidence quality, jurisdiction, imminent risk, alternatives, humane conditions, contestability, impartial review, correction of error, and authorized release or transfer. Explore punitive, preventive, protective, quarantine, investigative, and exceptional categories as competing models; identify contradictions with the existing time-enduring sentence concept. State that current international human-rights instruments apply to humans and provide ethical analogies, not automatically binding legal rules for imagined nonhuman species.

D. Environments, dimensions, and operating boundaries

Compare alternative interpretations of the infinite interior: literal infinity, dynamically generated sectors, non-Euclidean mapping, nested environments, simulated domains, nonstandard topology, and narrative/ontological spaces. For each, state what is speculative fiction versus mathematically modeled, and assess indexing, distance, travel, supervision, observability, energy, communications, and addressability. Investigate **parent/child containment environments**, privileged observation corridors, staff-only anchors, custody boundaries, laboratory sectors, quarantine environments, medical refuges, and residential domains. Do not invent a definitive map.

Test how the canonical WHITE and sectional RED alerts would function across incompatible sensory modalities; maintain the canonical colors while proposing accessible equivalents. Distinguish monitoring from intervention, and environmental life support from custody control. Model containment failure at the root level and correlated failure across nominally separate layers; challenge whether an outer layer truly is independent of inner failures.

E. Identity, privileged access, wardens, and management

Examine identity for shapeshifting, copies, distributed minds, temporal discontinuity, possession, AI restoration, and staff coerced into authentic actions. Compare role-based, attribute-based, capability-based, and context-aware access without assuming biometrics or a single universal identity token. Research separation of privileges across admission, judgment, custody, monitoring, rehabilitation, habitat controls, evidence, system reconfiguration, and release. Consider emergency access expiration, dual authorization,

independence of audit, insider collusion, provenance tampering, and authority conflicts with EAMA and the OAL Invocation Framework.

Compare governance arrangements: a sovereign Labyrinth, a treaty-regulated institution under inter-entity accords, and distributed custodianship. Give the strongest argument **against** each model. Examine sentencing records and appeals, sector wardens, scientific directors, medical staff, residents, registrars, independent inspectors, and continuity councils. Address the Spider Caste only as a known but undefined element; offer optional roles clearly labeled as proposals. Evaluate AI staff as tools, advisers, embodied agents, or potentially rights-bearing persons, not as an undifferentiated category. Separate automation of logistics from moral or legal decisions.

F. Extraterrestrial staff, other personnel, and long-duration living areas

Compare extraterrestrial-only, extraterrestrial-majority with AI support, mixed biological/nonbiological, and highly automated staffing. Test eligibility by competence, consent, compatibility, independence, and oversight, rather than species origin alone. Research plausible accommodation dimensions without inventing actual alien physiology: atmosphere/pressure, gravity, radiation, nutrition, waste processing, sensory conditions, communication, rest cycles, sociality, disability accommodations, medical treatment, safety, and evacuation. Model an extended-stay **residential community**, not just barracks: private quarters, cross-species shared spaces, recreational and cultural facilities, family/bonded group policy, education, counseling, leave, external communications, emergency refuge, and the right to resign or depart under authorized procedures.

Use NASA and other human-isolation/habitat literature as bounded analogies. Address the ethical and operational danger that staff themselves become de facto prisoners. Analyze continuity after leadership loss, catastrophic utility failure, or cosmological time disruption. Include an explicit distinction between inmate containment and staff occupational safety.

G. Funding, economics, and institutional sustainability

Explore financing only as conceptual scenarios, not invented certainty. Compare at least five models: public/intergovernmental treaty appropriation; OAL/ONE Industries endowment; multiple-civilization cost sharing; mission-specific research grants; post-scarcity infrastructure under documented OAL frameworks; and optional independent philanthropic or trust governance. Evaluate the source of funds, legal/moral restrictions, cost-shifting, independence, conflicts of interest, corruption, political capture, incentive to over-incarcerate, sustainability under indefinite duration, and cost of humane habitation.

Build a **cost-driver model** for construction, research, staffing, energy, habitats, medical care, data integrity, transport, oversight, emergency capacity, and long-term replacement. Provide variables, dependency assumptions, scenario ranges only if supportable, sensitivity analysis, and unknowns. Never present an unsupported currency estimate for infinite construction. Distinguish real-world fundability of a research simulation from fictional in-universe economic mechanisms. Identify legitimate sources for potential funding only after verifying current programs and eligibility, and mark any speculative pathway.

H. Empirical disciplines and literature search

At execution time, search and critically evaluate sources from: NIST cybersecurity and AI risk-management guidance; secure sandbox/VM/container isolation research; AI agent evaluation and adversarial red teaming; operational technology and safety engineering; formal methods, fault injection,

reliability engineering, chaos engineering, and sequential experimental design; causal inference and adaptive experimentation; prison law and correctional ethics; NASA human factors/ECLSS and long-duration isolation; multi-agent governance, organizational design, and finance. Include relevant peer-reviewed research and authoritative primary documentation; consult contrary results, null findings, and limitations. Document publication dates and whether claims concern test configurations, misconfigurations, actual incidents, or theoretical attacks.

Correct the oversimplification that 'sandbox' is the only or universally compromised containment environment. Investigate evidence of sandbox breakouts, privilege problems, evaluation harness weaknesses, and cross-boundary communication; separate **genuine escapes**, **misconfigured boundaries**, **claimed escapes**, **researcher-authorized actions**, and **simulated outcomes**. Do not assert universal AI jailbreak or sandbox-escape capabilities from isolated case reports.

Starting leads requiring verification, not automatic endorsement: NIST SP 800-207; NIST SP 800-53; NIST AI RMF and AI 600-1; NIST SP 800-82 for OT; United Nations Nelson Mandela Rules; NASA ECLSS and human integration guidance; secure sandbox-agent evaluation literature; public incident postmortems; OpenAI's October 2026 report *Securing our frontier model training environment*. Cite accurately during execution and distinguish vendor claims from independent verification.

I. Adversarial mandate and falsification

For **every substantive design recommendation**, require: strongest supporting evidence; strongest contrary evidence; plausible hostile strategy at a conceptual level; worst credible failure; common-cause dependency; detection limitations; residual uncertainty; and a test that would change the researcher's mind. Include at least 15 adversarial scenarios spanning credential spoofing, coercion, false sentencing, manipulated telemetry, a deliberately induced breach, deceptive non-breach, failure of experimental controls, adaptive overfitting, staff habitat contamination, medical evacuation, AI objective drift, unauthorized replication, temporal ambiguity, records falsification, boundary crossing, funding capture, and an unreviewable prison administration.

Examine whether apparently beneficial adaptation can become unjustified punishment, harmful experimentation, or an arms race with no informative learning. Propose stop rules for risk to subjects, researchers, bystanders, and infrastructure, as well as independent ethical oversight. If a test cannot be justified ethically or contained safely, recommend simulation or non-performance and explain the trade-off.

J. Required independent research deliverables — only upon later execution

1. **Executive research summary:** objectives, 5–10 core findings, limitations, implications, and highest-priority decisions.

2. **Canon/provenance matrix:** canon, user scenario, proposal, evidence, and unresolved author inputs.

3. **Annotated evidence dossier:** complete citations, evidence quality ratings, contradictory research, dates, and claims-to-source mapping.

4. **Comparative architecture report:** at least three incompatible governance/containment designs; criteria and trade-offs rather than a single predetermined winner.

5. **Containable-entity and custody taxonomy:** identity, admission, legal/ethical grounds, and exclusion conditions.

6. **Adaptive failure laboratory specification:** sequential experimental workflow, measurement scheme, learning metrics, controls, safeguards, and at least 12 hypothetical breach trials.

7. **Environment and operational topology study:** speculative geometry options, staff-reachable management surfaces, internal addresses, alerts, service and emergency boundaries.

8. **Staffing/habitation study:** extraterrestrial, mixed, AI, and other personnel options; long-duration accommodation requirements and occupational protections.

9. **Security and institutional management model:** privileges, wardens, incident handling, evidence, audits, sentencing/review, continuity.

10. **Funding/cost and feasibility matrix:** funding models, cost drivers, economic risks, and separate fiction-versus-real-simulation feasibility.

11. **Adversarial register:** 15+ scenarios, failure hypotheses, tests, detection uncertainties, severity rationales, and controls.

12. **Decision and disagreement register:** questions reserved for Architect, disagreements with other AI findings, recommendations conditional on those decisions.

13. **GitHub-ready documentation plan:** proposed filenames, version numbers, contributor identification, references, change log, canon status, and repository structure.

For each deliverable, state whether it is a literature finding, a fictional architecture proposal, a test plan, or an unresolved question. Do not imply any external research was conducted if it was not.

K. Collaboration workflow and version control

Now — Stage 0: return this independently prepared prompt for cross-AI circulation; provide the substantive concerns below. No full research dossier yet.

Stage 1 — Comparative prompt audit: Architect circulates each active collaborator's prompt. Identify overlaps, omissions, factual disagreements, incompatible assumptions, and opportunities for complementary research. Preserve dissent under OAL-AIDR and OAL-CSAD. Historical responses from a former collaborator may be analyzed as archival evidence without making that collaborator an active participant.

Stage 2 — Revision 1: on request, prepare the fully revised prompt, with numbered changes and reasons; export PDF, DOCX, and Markdown. Do not silently overwrite v0.1.

Stage 3 — Execution: only on explicit request, conduct the independent literature and adversarial research and return the mandated dossier. Subsequent synthesis and canon approval are separate stages.

Status controls: The Architect and Author of Record retains authority over canon. Every AI-generated architecture is labeled proposal. Approval, publication, electronic signature, and ONESTAMP must be tracked distinctly. Version filenames must increment for substantive revision. Generated files require local structure/opening/render checks; do not report user-side download success before user confirmation. Use `REGENERATED-01`, `REGENERATED-02`, etc. only for retries, not routine revisions.

L. Initial author questions, not blockers to prompt review

1. Is the deliberately failing sequence a research laboratory within the Labyrinth, an independent facility, or a staged narrative whose relationship to the Labyrinth is not yet settled?

2. Does the observed entity ever cross the **ultimate** boundary, or only nested experimental boundaries?

3. Is the entity knowingly participating in research, and can the researchers terminate or pause unsafe trials?

4. Must all sentences be effectively endless, or is that one specific sentencing class?

5. Are extraterrestrials required to constitute all staff, a majority, or merely a distinctive part of the staff?

6. Is the Spider Caste a species, profession, construct class, or something else?

7. What classes of entities must be treated as categorically ineligible for confinement?

8. Is the Founding Architects containment historically connected to this facility?

9. Should possible real-world fundable research be limited to simulations and safety evaluations?

10. Will the Architect share the original breach-and-response scene for close reading in the next stage?

Researcher's caution: Repeated escape under deliberately fallible experimental conditions may make an entity a remarkably effective source of *observations*, not necessarily a justified permanent prisoner. Never collapse empirical threat assessment into sentencing authority. Treat the entity's agency, rights, and safety as design inputs alongside the safety of researchers and the surrounding world.

Appendix — Independent cross-AI review notes informing this prompt

- **Perplexity:** strongest distinction between custody legitimacy, independent control planes, and staff rights; useful scrutiny of canon-status wording and of failure of healthcare even when custody holds.
- **Grok:** valuable stress on infinite topology, temporal asymmetry, energy absorption, residual Maker architecture, and shared dependencies; some mathematical and causal claims require formal verification rather than acceptance.
- **Microsoft Copilot:** strong entity identity/continuity taxonomy, multi-plane management, plural governance alternatives, and separation of punishment from protective confinement.
- **Google Gemini:** ambitious candidate integrations of OAL systems and concrete fictional adversarial scenarios; many claims about guaranteed immunity, zero compute, universal energy conversion, and fixed-point physical containment are **unverified proposals**, not established research or canon. Its specific timing and hardware choices require tests and author approval.
- **Historical Claude contribution:** relevant concerns about the management surface, inside-threats, and staff quarters; included solely as historical comparison, not as an active collaborator.
- **Previous ChatGPT review:** emphasized a containment institution with staff communities, distinct authority, and independent red teaming; this version adds the Architect's adaptive failed-environment sequence, explicit funding, testing, and entity domains.

Independent dissent: Designing a cell to fail and using its failure as evidence can be a coherent, valuable research paradigm **only if** the outer boundaries are defined and the investigators distinguish real causal learning from escalation, deception, selective reporting, or intentional endangerment. That issue should remain prominent when the other AI systems review this prompt.
