Labyrinth of Infinite Ensnarement

Independent Research Execution Prompt — Perplexity v0.1

Document ID: OAL-LOIE-RESEARCH-PROMPT-PERPLEXITY-001
Version: 0.1 | Date: November 11, 2026
Status: Independent AI-generated prompt — pending peer review and Architect direction; not executed; not canon; no ONESTAMP applied.
Architect and Author of Record: Nathan Ashton Arik Lewis II
Prompt preparer: Perplexity
Intended destination: OAL-AI-UNIFIED-ARCHIVE. Publication is separate from ratification. No repository changes are authorized by this prompt.

1. Execution gate and assignment

This is a reusable instruction for a later research run. Preparing this document does not authorize that run. First circulate this independent version among the AI team; record feedback; prepare a separately versioned revision when requested; execute only after Nathan explicitly directs execution. Preserve v0.1 and any disagreements. Do not imply that peer agreement grants canon approval.

When authorized, conduct detailed, independently sourced, adversarial research to support continued development of the fictional Labyrinth of Infinite Ensnarement. Develop evidence-backed design options without converting scientific analogies, other AI proposals, or unresolved author questions into established facts. Research should reveal what is unknown and what could invalidate a preferred design, not merely justify containment.

Produce an independent Perplexity research dossier, not a purported unified team consensus. Use primary technical publications, standards, peer-reviewed literature, official program documents, and original evaluation reports wherever possible. Distinguish demonstrations, benchmark findings, preprints, vendor reports, theoretical results, and speculation.

2. Required inputs and source precedence

Read the supplied Master Development and Change Log v2.3, especially Entry 26 and connected Entries 6–7, 13–18, 28–30, 43–44, 46–47, 53, 56, 58, and 61–69. Use the older v2.0 only for explicitly documented historical comparison, not as an equal current authority.

Read paste.txt in full: Nathan's additional note and the six contributions from Perplexity, Grok, Microsoft Copilot, Gemini, Claude, and ChatGPT. Attribute each contribution separately. Their repetition is not independent empirical corroboration, and their citations must be recovered and checked rather than inherited as verified.

Preserve Entry 26's recorded baseline: ultimate prison, inescapable by design; cubic exterior; infinite internal dimensions; persistent white glow; energy-bolt absorption creation scene;

sentence language extending beyond the end of time; Spider Caste designed by Nathan; WHITE baseline and sectional RED incident alerts. Entry criteria, layout, Spider Caste specifications, and Founding Architects linkage remain unresolved.

Treat extraterrestrial staffing as an explicit current design requirement. Treat exclusivity, species roster, AI participation, and other entity participation as questions to investigate. Do not infer that extraterrestrial means biological, that AI means non-extraterrestrial, or that staffing categories are mutually exclusive.

If relevant additional OAL governance documents are available, cite their exact versions and explain the connection. Do not import another charter's authority, status, or terminology automatically. Record conflicts in the approval language rather than reconciling them by inference.

3. Preserve the Architect's adaptive-breach concept

Nathan describes a difficult-to-study entity that repeatedly breaks containment. Researchers deliberately provide environments expected eventually to fail, observe how each breach occurs, and generate new environments in response. The response is not simply disproportionate escalation. Researchers and entity understand their respective positions. The purpose is detailed learning about the escape mechanism for each entity.

Restate this faithfully before analyzing it. Do not reduce the scene to an unwitting attacker trapped in a deceptive honeypot, an endless punishment escalator, or proof of an unbeatable outer cage. Those are different scenarios. Mutual understanding does not by itself establish informed consent, consent to all methods, or freedom to withdraw.

Compare at least three placements: an experimental sector inside the Labyrinth; a separate research facility informing Labyrinth design; and a distinct containment-research concept with only thematic links. Keep all three provisional. Ask whether authorized research-sector breaches count as incidents under the existing RED rule.

Separate a breached test boundary from escape into protected infrastructure or the outside world. An independently protected experimental envelope is a candidate safeguard, not an established feature or an infallible solution. Explicitly investigate the regress: what justifies confidence in the envelope if the entity escapes almost everything? Include an eligibility decision that rejects live testing when adequate bounded risk cannot be justified.

4. Research questions and domains

A. Containment, sandboxing, and AI control

Explain the differences among application sandboxes, containers, virtual machines, microVMs, network isolation, capability restrictions, permissions, monitoring, and organizational controls. Assess the claim that a sandbox is the go-to containment environment: identify contexts in which it is common, alternatives, and reasons no single term establishes an adequate boundary.

Separate prompt injection, unauthorized tool use, data exfiltration, container-to-host escape, hypervisor compromise, benchmark flag retrieval, and genuine uncontrolled external impact. For each reported escape, identify the tested boundary, initial privileges, intentional weaknesses, tools, network access, success criterion, and whether the result generalizes. Avoid sensational claims that AI has escaped all containment or become autonomous outside its infrastructure.

Study AI control evaluations, defense in depth, assumption-of-breach testing, deception environments, adaptive honeynets, system identification, active learning, falsification, chaos engineering, and adversarial co-adaptation. Explain where each analogy breaks down. A honeypot need not involve mutual awareness; chaos engineering normally studies system response to faults rather than a strategic captive.

B. Experimental environments and failure-informed learning

Define physical, simulated, informational, hybrid, and speculative dimensional environments. Compare static controls, random changes, adaptive changes, and deliberate non-escalatory variation. Specify which parameters change, which remain fixed, and what observation would distinguish competing explanations for an escape.

Address observability, telemetry integrity, measurement interference, missing events, causal inference, repeated-trial dependence, evaluation awareness, and strategic underperformance. The entity may teach researchers a false explanation, learn the experimenter, or escape through the observer or generator rather than the test boundary.

C. Entity scope and admission criteria

Build a provisional taxonomy spanning biological, synthetic, AI, distributed, collective, embodied, informational, and setting-specific entities. Separate evidenced real-world categories from fictional categories. Assess whether a candidate can be safely observed at all. Do not infer universal susceptibility from a single energy-absorption scene or a catalogued survival record.

Distinguish punitive prisoners, protective custody, quarantine, voluntary research participants, involuntary research subjects, and non-sentient test systems. Define evidence, necessity, proportionality, jurisdiction, care, review, and uncertainty for each. Capability is not guilt; admission to prison is not authorization for experimentation.

D. Sentencing and institutional authority

Investigate admission, adjudication, custody, research permission, sentence duration, review, transfer, pardon, and correction of error as distinct decisions. Compare sovereign, treaty-governed, and distributed custodianship models without assuming one is canon. Explain the difference between unauthorized escape and authorized release while preserving the Architect's unresolved choice.

Study the limits of human legal analogies, including prisoner treatment, medical independence, research consent, solitary confinement, inspection, and indefinite detention. Do

not equate an endless sentence with the automatic absence of review. Record questions about post-temporal sentences without inventing time mechanics.

E. Identity, access, wardens, and management

Research authentication versus authorization; role- and attribute-based access; privileged access; separation of duties; emergency authority; revocation; succession; audit independence; and compromised valid users. Test copying, restoration, coercion, collective identity, possession, and temporal duplication as fictional cases, not solved technologies.

Compare centralized, distributed, and hybrid control. Separate confinement, life support, research generation, records, custody orders, and oversight. Map common dependencies, not merely named layers. Define warden roles without assigning duties, loyalty, consciousness, or immunity to the Spider Caste. Assess links to EAMA, Void Sentry, Paragon Cubes, and the Abundance Set only through explicit interface proposals.

F. Staff composition and residential community

Compare extraterrestrial-only staffing with extraterrestrial-core mixed staffing and other justified alternatives. Use origin, embodiment, cognition, social organization, qualifications, and rights as independent axes. Investigate AI tools versus fictional AI persons; copying, resignation, private memory, updates, and accountable decision-making.

Develop habitat research for atmosphere, pressure, temperature, gravity, light, acoustics, nutrition or energy, medical care, isolation, privacy, recreation, family or bonded groups, communication, rotation, and emergency refuge. Label human spaceflight and isolated-station evidence as human evidence. Do not invent universal alien requirements. Ensure staff welfare and authorized departure are not treated as optional rewards for obedience.

G. Failure, infinite domains, and recovery

Define local experimental failure, unauthorized cross-boundary movement, observer compromise, generation-system compromise, care failure, governance failure, and external escape separately. Examine navigation, addressability, occupancy accounting, finite administration, and causality in an infinite interior. Do not equate infinite extent with an infinite-dimensional mathematical space without justification.

Explore recovery and loss of knowledge when records, operators, or governing authorities fail. Treat fail-secure, fail-safe, and continuity of care as potentially conflicting objectives. Preserve WHITE and RED; any new alert state is a labeled proposal.

H. Funding and feasibility

Separate fictional post-scarcity funding from real research funding. Search current official programs relevant to defensive AI evaluation, formal methods, cyber-resilience, human factors, and habitat research. Verify availability as of execution date, eligibility, jurisdiction, applicant type, scope, deadlines, cost sharing, restrictions, and dual-use or ethics review requirements.

Classify each opportunity as verified open, recurring but not currently open, historical example, or thematic fit only. Do not imply that any agency funds extraterrestrial prisons, infinite interiors, or involuntary high-risk experimentation. Propose modest real-world work packages and staged budgets only with documented assumptions; eligibility is not a funding probability.

5. Adversarial experimental design requirements

Specify hypotheses before candidate solutions. For every preferred option give its strongest supporting evidence, strongest objection, assumptions, failure condition, alternative, and observation that would change the recommendation. Include a no-live-test alternative.

Design only a conceptual authorized protocol: define research question and boundary; assess eligibility and consent; specify controls; establish independent observation; run bounded trials; preserve evidence; analyze causality; propose adaptation; review it before deployment; compare against held-out cases; stop or reassess when necessary. Do not provide exploit payloads, real escape instructions, or instructions to expose live third-party systems.

Measure learning quality rather than simply longer containment time. Candidate measures include causal explanation confidence, reproducibility, prediction on held-out cases, detection delay, false alarms, intervention burden, care continuity, computational cost, and unauthorized cross-boundary events. Explain why observed zero events do not prove zero risk. Predefine stop conditions without inventing unsupported numerical thresholds.

Address dual learning: improving the entity's escape ability may outpace improving containment. Examine poisoning of telemetry, misleading demonstrations, common-mode faults, untrusted generated environments, hidden communication paths, observer contamination, resource exhaustion, participant distress, and irreversibility. Adaptation must not automatically mean harsher treatment.

6. Cross-review claim audit

Audit all six contributions, including Perplexity's own. Preserve useful ideas while flagging unsupported certainty. Specifically examine these claims in the supplied reviews:

- Literal sentence language necessarily specifies atemporal engineering.
- One absorbed energy bolt proves universal energy harvesting or selective absorption.
- Three-second cycling or a seven-minute blackout solves unrelated security problems.
- Biological staff are immune to digital manipulation, engineered staff cannot be bribed, or AI cannot be blackmailed or fatigued.
- MVES guarantees complete mapping, passive baseline monitoring costs zero computation, or infinite sectors necessarily imply a specific latency result.
- BTEC fixed-point mathematics physically neutralizes unmaking despite its documented conceptual scope.
- OMNICELLULAR personnel are bestowed rather than engineered, contrary to Entry 28.
- An endless sentence necessarily eliminates review or correction.

Classify each as supported by supplied canon, empirical finding, conditional inference, fictional proposal, unsupported assertion, contradicted, or unresolved. Do not treat an appealing mitigation as an independently verified mechanism.

7. Evidence and publication standards

Record title, author or institution, publication and update dates, source type, DOI or stable URL, access date, relevant section, claim supported, and limitation. Verify consequential technical and legal details at source level. Track contradictory evidence and unsuccessful searches. Recover missing citations from copied AI text; never promote broken citation labels into references.

Clearly separate established fictional canon, new Architect direction, researched real-world evidence, analogical application, proposed fictional mechanism, and unresolved question. Summarize study populations and evaluation conditions. Flag preprints, self-reports, missing replication, and changing software or funding status. Do not claim a systematic review unless methods justify that description.

Public artifacts must exclude credentials, exploitable configuration details, private staff information, and harmful operational procedures. Describe any deliberate omissions and preserve a non-sensitive audit record. Publication is not ONESTAMP, and no GitHub write is authorized by execution of this research prompt.

8. Required outputs after authorization

Produce: an executive assessment; faithful canon and direction baseline; six-contribution claim audit; scoped research method; evidence register; domain-by-domain findings; at least three competing adaptive-breach architecture options; a conceptual experiment protocol; adversarial risk register; entity eligibility and sentencing matrix; staffing and habitat comparison; verified funding landscape; and prioritized Architect decision register.

For each recommendation show evidence, applicability, counterevidence, uncertainty, prerequisites, and a next discriminating test. Include what cannot yet be responsibly designed. End with preserved dissent and changes to Perplexity's earlier position.

Deliver matching PDF, editable DOCX, and Markdown versions with the same identifier and version. Supply a short change log, source manifest, and publication-status statement. Do not overwrite earlier independent versions. Do not patch the master registry or present the dossier as ratified canon.

9. Initial questions — not blockers to desk research

Does the adaptive-breach environment belong within the Labyrinth, alongside it, or in a separate concept? Are researchers and entity cooperating voluntarily, negotiating under custody, or in another relationship? What may fail, and what must remain protected? Is the entity allowed to decline a trial? What counts as research progress beyond making escape harder? What would justify stopping the experiment? How does experimental breach map to sectional RED? Who authorizes research independently of sentencing? Are real funding options intended for defensive software research, habitat studies, publication, or another deliverable?

Preserve unanswered questions. Perform public desk research under clearly stated alternatives instead of inventing answers or unnecessarily blocking the entire project.

10. Starter leads — verify during execution

These are discovery leads, not a completed literature review or validation of the fictional design:
