My original Prompt
SLIAP: SPECIES LEVEL INFORMATION ACCESS PROTOCOL

PRELIMINARY RESEARCH, GOALS, AND ADVERSARIAL ANALYSIS

So i was thinking about how i have to design SLIAP. My first challenge was that i dont want to approach this as though humans are the only species, as though humans are intellectually superior, or that they should have universal power to regulate, control, or determine protocols for SLIAP. Historically humans have had the mindset that they are superior, and aside from the proliferation of wars that drive human conflicts and attempts at conquest, the goal in designing this protocol is not to restrain the idea of a species to a human centered view. Humans are A species, a race, NOT THE ONLY SPECIES or race. Determining what information and access you have requires stepping outside of that mindset and considering a perslective and point of view completely outside of your own. The goal of this prompt is to initiate research to help inform the design and development of SLIAP: The Species Level Information Access Protocol. The goal of this prompt is to step ouside of a single point of view and gain perspective for how a system that regulates inflrmation and access between species/races/civilizations should be designed. It is not to assume that the human centered approach will be universally acceppted or the basis of this research or foundational framing. Your first task is to design a detailed and structured prompt of your own that will support this goal. I will share each prompt generated with each Ai that I collaborate with and request that they generate a deliverable following the initial prompt review and produce a research deliverable in PDF, Docx, and Markdown that I will publish in a dedicated folder on Github.

Responses

FROM CHATGPT

Yes. The core design problem you are identifying is larger than “information security between humans.” SLIAP has to remain coherent even when the parties differ radically in biology, cognition, technology, values, temporal scale, communication, political organization, or even in what they consider an “individual,” “species,” “information,” “consent,” or “harm.”
I would therefore make the first research phase deliberately **pre-protocol**: before deciding what SLIAP permits, the researchers must examine whether the concepts used to construct it are themselves anthropocentric.
Below is the prompt I would circulate to each collaborating AI independently.

SLIAP: SPECIES-LEVEL INFORMATION ACCESS PROTOCOL

Preliminary Research, Foundational Analysis, and Adversarial Design Exercise

Research Status

Preliminary / Pre-Protocol Research
This assignment is intended to inform the eventual design of the **Species-Level Information Access Protocol (SLIAP)**. It does not establish final SLIAP doctrine, rules, governance structures, classifications, or access permissions.
The purpose of this phase is to investigate the problem before prematurely designing the solution.

---

1. CENTRAL RESEARCH QUESTION

How should an information-access protocol be designed when the entities interacting with it may belong to different species, civilizations, forms of intelligence, biological architectures, technological systems, cultures, worlds, environments, or modes of existence—and no single species is presumed to possess universal authority over the others?
Develop an independent research framework addressing this question.
Do **not** assume that humans are:

- the only intelligent species;
- the most intelligent species;
- the most technologically advanced species;
- the proper governing authority for all species;
- the default reference model for intelligence;
- the default reference model for consciousness;
- the default reference model for morality;
- the natural owner of information;
- entitled to unrestricted observation of other species;
- entitled to determine what other species may know;
- universally recognized as legitimate authorities;
- entitled to establish unilateral rules governing interspecies information exchange.

Humans should be treated as **one possible participating species or civilization among others**.

The research should therefore attempt to reason from multiple possible frames of reference rather than constructing a human information-security framework and merely extending it to hypothetical nonhuman entities.

---

2. PURPOSE OF SLIAP

For purposes of this research exercise, SLIAP is provisionally defined as:

> **A framework or protocol governing the discovery, classification, disclosure, acquisition, transmission, restriction, authentication, verification, preservation, transformation, and use of information when information relationships cross meaningful species-, civilization-, intelligence-, biological-, technological-, or ontological boundaries.**

This definition is deliberately provisional.
You are encouraged to challenge it.
Determine whether the phrase **Species-Level Information Access Protocol** adequately describes the problem or whether the eventual system requires additional conceptual layers.

---

3. FOUNDATIONAL PRINCIPLE

SLIAP must not begin with the premise:

> "What information should humans allow another species to access?"

That framing presupposes ownership and authority.
Instead begin with questions such as:

- Who possesses the information?
- Who generated it?
- Who discovered it?
- Who is represented by it?
- Who is affected by its disclosure?
- Who claims jurisdiction over it?
- Is the claim legitimate?
- According to whom?
- What happens when legitimacy itself is disputed?
- Can information actually be owned?
- Can information about another species be controlled exclusively by the observer?
- Does observation create rights?
- Does discovery create rights?
- Does creation create rights?
- Does possession create rights?
- Can an entire species consent?

- Can an entire civilization refuse?
- Who speaks for either?
- What happens when there is no recognized representative?

Treat these questions as unresolved.

---

4. REJECT THE SINGLE REFERENCE FRAME

A central requirement of this assignment is to investigate how a protocol can operate when participants do not share the same reference frame.
Consider actors that differ in:

- sensory systems;
- cognition;
- language;
- memory;
- lifespan;
- processing speed;
- collective versus individual intelligence;
- biological organization;
- machine organization;
- social organization;
- concepts of privacy;
- concepts of identity;
- concepts of property;
- concepts of secrecy;
- concepts of consent;
- concepts of truth;
- concepts of evidence;
- concepts of authority;
- concepts of time;
- concepts of individuality;
- concepts of death;
- concepts of communication;
- tolerance for uncertainty;
- ability to predict consequences;
- technological capability;
- ability to copy or transform information.

Ask whether a protocol built around one civilization's concepts would even be intelligible to another.

---

5. DEFINE THE PARTICIPANTS

Do not restrict the analysis to familiar extraterrestrial humanoids.
Develop a broad actor taxonomy.
At minimum examine:

Biological Intelligence

Humans, animals, hypothetical extraterrestrial organisms, distributed organisms, colony organisms, hive systems, microbial collectives, ecological intelligences, and other biological possibilities.

Artificial Intelligence

Individual AI systems, distributed AI, autonomous machine civilizations, recursively improving systems, digital organisms, synthetic minds, and machine collectives.

Hybrid Intelligence

Human-machine civilizations, cybernetic organisms, biological-computational collectives, uploaded minds, augmented organisms, and mixed-origin societies.

Collective Intelligence

Hive minds, swarm intelligence, civilization-scale computation, planetary intelligence, ecological networks, or entities where the distinction between individual and collective is unclear.

Unknown Intelligence

Actors whose cognitive architecture cannot initially be interpreted.
SLIAP must include a category for entities that cannot yet be reliably classified.

---

6. DO NOT EQUATE SPECIES WITH POLITICAL UNITY

Investigate a major structural problem:
A species is not necessarily a government.
Humanity demonstrates this immediately.
Humans belong to one biological species yet exist within:

- different nations;
- different governments;
- different cultures;
- competing institutions;
- corporations;
- militaries;
- scientific communities;
- religious communities;
- decentralized networks;
- individuals;
- criminal organizations;
- alliances;
- rival political systems.

Therefore investigate whether **species-level authorization** is itself meaningful.
Ask whether SLIAP needs separate concepts for:

- organism;
- individual;
- group;
- population;
- culture;
- institution;
- government;
- civilization;
- species;
- multispecies coalition;
- planetary authority;
- distributed intelligence.

Do not collapse these categories into one another.

---

7. THE REPRESENTATION PROBLEM

Who has authority to represent a species?
Investigate cases where:

- one government claims to represent an entire species;
- multiple governments disagree;
- no planetary government exists;
- a technological elite claims superior authority;
- a military controls first contact;
- corporations control communication infrastructure;

- scientists possess information governments do not;
- one faction secretly communicates with another civilization;
- an AI speaks on behalf of humans without authorization;
- one civilization falsely claims universal representation;
- a collective intelligence cannot identify an individual spokesperson;
- a species lacks political institutions entirely.

Determine how SLIAP could distinguish representation from mere capability.

---

8. INFORMATION CATEGORIES

Develop a preliminary information taxonomy appropriate for interspecies or intercivilizational exchange.
Possible categories should include, but not be limited to:

- public information;
- cultural information;
- scientific information;
- historical information;
- biological information;
- genetic information;
- ecological information;
- medical information;
- geographic information;
- astronomical information;
- technological information;
- defensive information;
- military information;
- infrastructure information;
- communications architecture;
- cryptographic systems;
- vulnerabilities;
- governance structures;
- behavioral models;
- psychological information;
- predictive models;
- artificial intelligence architectures;
- autonomous weapons knowledge;
- replication technologies;
- energy technologies;
- propulsion technologies;
- surveillance systems;

- catastrophic-risk knowledge;
- existential-risk information.

Do not automatically conclude that any category must be restricted.
Instead determine what characteristics might justify different access treatments.

---

9. INFORMATION ASYMMETRY

Analyze situations in which one civilization knows vastly more about another.
Examples:

- Civilization A has observed Civilization B for 10,000 years.
- Civilization B has only just discovered Civilization A.
- One civilization can decode the other's communications.
- The weaker civilization cannot understand the stronger civilization's communications.
- One civilization possesses predictive behavioral models of another.
- One civilization possesses complete genetic information about another.
- One civilization has infiltrated another's information infrastructure.
- A civilization does not know it is being observed.

Ask whether possession of information creates obligations.
Could there be a concept analogous to **informational power imbalance**?
Should asymmetry itself influence access rights?

---

10. CAPABILITY ASYMMETRY

Do not assume reciprocal information exchange produces reciprocal consequences.
A basic scientific fact provided to one civilization may be harmless.
The same information given to another could enable:

- planetary destruction;
- biological manipulation;
- mass surveillance;
- autonomous weapons;
- uncontrolled replication;
- irreversible environmental alteration.

Conversely, apparently dangerous information may already be trivial to an advanced civilization.
Therefore distinguish:
information sensitivity
from

recipient capability
from
likely consequence.
Investigate whether access decisions should consider all three.

---

11. INFORMATION HAZARDS

Research the concept of information hazards and extend it beyond human information-security assumptions.
Examine knowledge that may create danger merely by becoming known.
Potential classes include:

- technological hazards;
- biological hazards;
- strategic hazards;
- psychological hazards;
- memetic hazards;
- sociological hazards;
- ecological hazards;
- artificial-intelligence hazards;
- coordination hazards;
- existential hazards.

Investigate an especially difficult possibility:

> What if the recipient is better qualified than the information controller to determine whether the information is dangerous?

Who decides?

---

12. THE TECHNOLOGICAL INEQUALITY PROBLEM

Examine civilizations at radically different stages of development.
Possible relationships include:

- preindustrial ↔ interstellar;
- biological ↔ post-biological;
- planetary ↔ interplanetary;
- non-digital ↔ computational;
- individual intelligence ↔ civilization-scale intelligence.

Investigate whether technological disparity justifies information restriction.
Then adversarially challenge that conclusion.
For example:

> “We restrict this information for your protection.”

may represent legitimate harm prevention.
It may also represent paternalism, domination, technological monopoly, or colonial control.
Develop criteria for distinguishing them.

---

13. INFORMATIONAL COLONIALISM

Investigate whether information systems can reproduce colonial relationships.
Potential behaviors include:

- extracting knowledge without consent;
- cataloging another species;
- patenting discoveries derived from another civilization;
- restricting the civilization from accessing knowledge derived from itself;
- observing without disclosure;
- defining another civilization using foreign categories;
- imposing an external identity classification;
- controlling communication infrastructure;
- monopolizing translation;
- suppressing indigenous knowledge systems;
- claiming scientific ownership of biological or cultural information.

Determine whether SLIAP requires safeguards against **informational colonialism**.

---

14. TRANSLATION IS NOT NEUTRAL

Investigate translation as a security and governance problem.
Translation systems can:

- omit information;
- distort information;
- insert assumptions;
- impose categories;
- create false equivalence;
- destroy ambiguity;
- introduce ambiguity;
- manipulate tone;

- alter intent.

If civilizations require translation systems to communicate, those systems may become some of the most powerful components of SLIAP.
Ask:
Who creates the translator?
Who verifies it?
Who audits it?
Can either civilization detect manipulation?
Could translation itself constitute an access-control layer?

---

15. AUTHENTICATION ACROSS SPECIES

Conventional authentication methods may not generalize.
Investigate possible mechanisms for establishing:

- identity;
- continuity of identity;
- origin;
- authority;
- delegation;
- authenticity;
- provenance.

Consider participants that do not possess:

- fingerprints;
- DNA as humans understand it;
- stable physical bodies;
- permanent identities;
- individual consciousness;
- centralized governments;
- digital cryptographic infrastructure.

Determine what an authentication framework would require without assuming human identity architecture.

---

16. CONSENT

Investigate consent across radically different entities.
Questions include:

- Can an individual authorize species-level disclosure?
- Can a government?
- Can a majority?
- Can a planetary government?
- Can future generations be bound?
- Can extinct civilizations retain informational rights?
- Can non-sentient species possess informational protections?
- Can ecosystems possess informational interests?
- Can collective minds consent?
- Can a species revoke consent after information has already been copied?

Separate:
consent to communication
from
consent to observation
from
consent to collection
from
consent to storage
from
consent to analysis
from
consent to redistribution.

---

17. REVERSIBILITY

Information disclosure is often irreversible.
Once information is learned, transmitted, or copied, it may no longer be retractable.
Therefore examine the distinction between:

- reversible actions;
- partially reversible actions;
- irreversible actions.

Determine whether SLIAP should impose higher evidentiary or governance requirements before irreversible disclosures.

---

18. RECIPROCITY

Evaluate whether reciprocal access should be a foundational principle.

Possible rule:

Civilization A receives equivalent access to Civilization B's information.

Challenge this rule.
Equality of access may not create equality of consequences.
Research alternative concepts such as:

- reciprocity;
- proportionality;
- symmetry;
- equitable exchange;
- capability-adjusted exchange;
- negotiated exchange;
- unilateral disclosure;
- common knowledge.

Determine where each might be appropriate.

---

19. NON-INTERFERENCE

Investigate a possible non-interference principle.
Should advanced civilizations avoid influencing less technologically developed civilizations?
Analyze arguments both for and against such a principle.
Potential benefits:

- cultural autonomy;
- reduced technological disruption;
- reduced exploitation.

Potential harms:

- withholding lifesaving information;
- tolerating preventable catastrophes;
- institutionalizing technological inequality;
- preserving oppressive systems under the justification of non-interference.

Do not assume non-interference is inherently ethical.

---

20. THE RIGHT TO KNOW VS. THE RIGHT NOT TO KNOW

Investigate whether civilizations may possess:

- a right to information;
- a right to refuse information;
- a right not to be observed;
- a right to remain undiscovered;
- a right to conceal themselves;
- a right to control information about themselves.

Consider a civilization that deliberately does not want knowledge of other civilizations.
Would forced contact itself violate information autonomy?

---

21. OBSERVATION

Ask whether observation constitutes access.
If a civilization can remotely observe another planet, does it need permission?
What about:

- telescope observations;
- intercepted radio;
- intercepted networks;
- probes;
- surveillance;
- genetic sampling;
- cultural modeling;
- predictive simulation?

Determine where observation becomes intrusion.

---

22. MODELING AND DIGITAL RECONSTRUCTION

Consider a civilization constructing a highly accurate simulation of another civilization.
The model predicts:

- political behavior;
- military responses;
- individual decisions;
- cultural evolution.

Does the modeled civilization possess any rights regarding that model?
Does high predictive accuracy create a new form of informational power?
Should synthetic representations receive access restrictions?

---

23. DISCOVERY

Investigate whether discovering information gives the discoverer rights over it.
Example:
Civilization A discovers a phenomenon produced by Civilization B but unknown to Civilization B.
Who controls the information?
Consider competing principles:

- discovery;
- origin;
- possession;
- affected-party interest;
- common knowledge;
- scientific commons.

---

24. UNKNOWN-RISK CONTACT

Design principles for interaction when almost nothing is known about the other entity.
A protocol should not require complete understanding before functioning.
Analyze a possible progression such as:
UNKNOWN → OBSERVED → DETECTED → CONTACTED → PARTIALLY CHARACTERIZED → VERIFIED → NEGOTIATING → ESTABLISHED RELATIONSHIP
Challenge this sequence and propose alternatives.

---

25. TRUST MUST NOT BE BINARY

Avoid reducing participants to:
TRUSTED / UNTRUSTED
Develop multidimensional trust.
Possible dimensions:

- identity confidence;
- communication reliability;

- historical behavior;
- agreement compliance;
- technical capability;
- transparency;
- predictability;
- information-handling behavior;
- hostile capability;
- hostile intent;
- uncertainty.

A civilization may score differently across each dimension.

---

26. ADVERSARIAL ANALYSIS

Red-team every major principle proposed.
Assume actors may attempt to manipulate SLIAP.
Attack scenarios should include:

- false identity;
- false species classification;
- false civilization representation;
- forged authorization;
- compromised translators;
- hidden information channels;
- deliberate misinformation;
- selective disclosure;
- technological deception;
- asymmetric surveillance;
- coercive agreements;
- forced consent;
- compromised governance bodies;
- impersonation;
- manufactured emergencies;
- false existential threats;
- strategic withholding;
- information laundering through third parties.

Determine how SLIAP distinguishes legitimate uncertainty from intentional deception.

---

27. ADVERSARIAL GOVERNANCE

Do not assume the organization administering SLIAP is trustworthy.
Ask:
What happens if the regulator itself becomes the threat?
Model scenarios involving:

- regulatory capture;
- authoritarian control;
- corruption;
- species favoritism;
- cultural bias;
- secret classification;
- unilateral rule changes;
- fabricated security threats;
- permanent emergency powers;
- surveillance abuse;
- access monopolies.

Develop safeguards against the protocol's own administrators.

---

28. THE DOMINANT-CIVILIZATION PROBLEM

Imagine one civilization becomes overwhelmingly more powerful than every other participant.
SLIAP should not function merely because powerful actors voluntarily behave well.
Ask whether a protocol can meaningfully constrain an actor that does not need to obey it.
Distinguish:
technical enforcement
from
legal enforcement
from
diplomatic enforcement
from
normative legitimacy.

---

29. MULTISPECIES GOVERNANCE

Explore governance models.
Examples:

- unanimous agreement;
- representative councils;
- rotating governance;
- federated systems;
- treaty networks;
- distributed consensus;
- independent arbitration;
- constitutional limitations;
- cryptographically enforced governance;
- species-specific jurisdictions;
- civilization-specific jurisdictions;
- information-domain jurisdictions.

Do not automatically recommend democracy or any human political system.
Evaluate each architecture according to its assumptions.

---

30. LEGITIMACY

Develop a theory of legitimacy appropriate for SLIAP.
Possible sources of legitimacy include:

- consent;
- participation;
- transparency;
- reciprocity;
- procedural fairness;
- distributed authority;
- accountability;
- verifiability;
- non-domination.

Investigate whether legitimacy can exist without shared morality.

---

31. MINIMUM COMMON GROUND

What is the smallest conceptual foundation necessary for interspecies information governance?
Potential candidates include:

- identity;
- communication;
- causality;

- preference;
- agency;
- harm;
- reciprocity;
- predictability.

Do not assume these concepts are universal.
Determine what happens if even these assumptions fail.

---

32. PROTOCOL FAILURE CONDITIONS

Define circumstances under which SLIAP should admit:

No reliable access determination can currently be made.

Possible reasons:

- insufficient information;
- unverifiable identity;
- untranslatable communication;
- unknown consequences;
- contested authority;
- conflicting jurisdiction;
- unstable recipient;
- unknown technological capability.

A mature protocol must support uncertainty rather than forcing an answer.

---

33. ESCALATION STATES

Investigate whether SLIAP requires defined operational states such as:

- routine exchange;
- disputed access;
- heightened uncertainty;
- suspected compromise;
- confirmed deception;
- diplomatic conflict;
- active hostility;
- existential emergency.

Determine whether restrictions should automatically change during escalation.
Then investigate how emergency systems could be abused.

---

34. HISTORICAL HUMAN ANALOGUES

Use human history cautiously as a source of lessons, not as a universal model.
Relevant topics may include:

- colonialism;
- first-contact encounters;
- indigenous sovereignty;
- cultural appropriation;
- intelligence sharing;
- espionage;
- arms-control agreements;
- nuclear nonproliferation;
- biological security;
- cybersecurity;
- diplomatic immunity;
- international law;
- scientific openness;
- classification systems;
- privacy law;
- data sovereignty;
- export controls.

Identify what these systems teach us.
Also identify where human analogies fail.

---

35. NONHUMAN EARTH ANALOGUES

Research biological systems that challenge human assumptions about intelligence and communication.
Potential examples include:

- cetaceans;
- elephants;
- corvids;
- primates;
- cephalopods;
- eusocial insects;
- fungal networks;

- microbial communication;
- distributed ecological systems.

Do not anthropomorphize.
Use the research to identify how cognition, communication, individuality, and coordination can differ from familiar human models.

---

36. PHILOSOPHICAL FOUNDATIONS

Examine relevant fields including:

- epistemology;
- philosophy of information;
- ethics;
- political philosophy;
- philosophy of mind;
- philosophy of language;
- posthumanism;
- animal ethics;
- environmental ethics;
- xenoethics or extraterrestrial ethics where scholarly work exists;
- information ethics.

Explicitly identify disagreements between philosophical frameworks.
Do not manufacture consensus.

---

37. INFORMATION SECURITY FOUNDATIONS

Investigate established concepts including:

- confidentiality;
- integrity;
- availability;
- authentication;
- authorization;
- provenance;
- nonrepudiation;
- least privilege;

- zero trust;
- capability security;
- mandatory access control;
- attribute-based access control;
- data classification;
- compartmentalization;
- information-flow control.

For each concept ask:
Does this concept remain valid at species/civilization scale?
Classify findings as:

- directly transferable;
- transferable with modification;
- context-dependent;
- anthropocentric assumption;
- inadequate;
- unresolved.

---

38. POSSIBLE SLIAP ACCESS MODEL

Do not reduce SLIAP to conventional security clearance levels.
Investigate multidimensional authorization.
Possible dimensions include:
ENTITY × IDENTITY × AUTHORITY × INFORMATION × PURPOSE × CAPABILITY × CONSEQUENCE × CONSENT × CONTEXT × TIME × TRUST × REVERSIBILITY
Determine whether an access decision could conceptually resemble:
Access Decision = f(Entity, Information, Authority, Purpose, Capability, Consequence, Consent, Context, Trust, Uncertainty)
Do not treat this formula as established.
Critique it and improve it.

---

39. ACCESS IS NOT ONLY YES OR NO

Explore outcomes beyond:
ALLOW / DENY
Possibilities include:

- allow;
- deny;

- defer;
- negotiate;
- redact;
- abstract;
- summarize;
- rate-limit;
- compartmentalize;
- transform;
- provide supervised access;
- disclose incrementally;
- require reciprocal disclosure;
- require independent review;
- release after capability changes;
- release after time delay;
- release when risk conditions change.

Determine whether progressive disclosure should become a foundational SLIAP mechanism.

---

40. INFORMATION TRANSFORMATION

Ask whether SLIAP may permit information while restricting its resolution.
For example:
Instead of transferring an engineering blueprint, provide scientific principles.
Instead of exposing genetic records, provide aggregate biological information.
Instead of giving exact infrastructure coordinates, provide regional information.
Investigate **information transformation as access control**.

---

41. TEMPORAL ACCESS

Information sensitivity changes over time.
Develop models for:

- temporary secrecy;
- delayed disclosure;
- automatic review;
- declassification;
- technological maturity thresholds;
- event-triggered release;
- permanent restrictions.

Determine who controls those transitions.

---

42. PROVENANCE

SLIAP may require extremely strong information provenance.
Investigate how information could retain records of:

- origin;
- transformations;
- translations;
- custodians;
- permissions;
- restrictions;
- access history;
- confidence;
- disputes.

Also investigate whether provenance systems create surveillance risks.

---

43. RIGHT TO CHALLENGE

Any actor denied information should potentially be able to ask:

- Why?
- According to what rule?
- Based on what evidence?
- Who made the decision?
- Can the decision be appealed?
- When will it be reconsidered?

Determine whether **contestability** should be a core SLIAP principle.

---

44. RIGHT TO DISSENT

The research itself must preserve disagreement.
When experts, sources, philosophies, or simulated civilizations disagree, record the disagreement.
Do not collapse competing positions into artificial consensus.

For major unresolved issues provide:
Position A
Position B
Position C, where appropriate.
Then identify evidence and assumptions supporting each.

---

45. EDGE CASES

Construct difficult cases designed to break the protocol.
At minimum include:

1. A peaceful but overwhelmingly advanced civilization.
2. A technologically primitive civilization requesting advanced weapons knowledge.
3. A hostile civilization requesting medical knowledge.
4. A friendly civilization requesting another civilization's biological database.
5. A distributed hive intelligence with no individuals.
6. A machine civilization that copies itself continuously.
7. A civilization whose concept of privacy does not exist.
8. A civilization that considers secrecy inherently hostile.
9. Two civilizations claiming ownership of the same information.
10. A civilization requesting information capable of creating artificial superintelligence.
11. A civilization facing extinction unless restricted information is released.
12. A powerful civilization claiming emergency authority over weaker civilizations.
13. A non-sentient species whose biological information is commercially valuable.
14. An unknown entity whose communication cannot yet be translated.
15. Humanity requesting access to information another civilization considers forbidden.

For every scenario analyze the issue from multiple parties' perspectives.

---

46. INVERT THE HUMAN PERSPECTIVE

Perform dedicated inversion exercises.
Instead of asking:

> Should humans provide technology to extraterrestrials?

Ask:

> Should a civilization one million years more advanced than humanity provide its technology to humans?

Instead of:

> Should humans study an alien species?

Ask:

Should another civilization be permitted to continuously observe, model, catalogue, and experiment upon humans without human knowledge?

Instead of:

Can humans classify another species as dangerous?

Ask:

Under what conditions could another species classify humanity as dangerous?

Use these inversions to expose hidden assumptions.

---

47. ADVERSARIAL SELF-CRITIQUE

After developing your proposed framework, attack your own work.
Identify:

- anthropocentric assumptions;
- Western political assumptions;
- democratic assumptions;
- individualist assumptions;
- technological assumptions;
- biological assumptions;
- economic assumptions;
- legal assumptions;
- linguistic assumptions;
- moral assumptions.

For each, determine whether it is necessary or merely familiar.

---

48. RESEARCH REQUIREMENTS

Conduct multidisciplinary research.
Where possible prioritize:

1. peer-reviewed scholarship;
2. academic books;
3. standards bodies;
4. governmental or intergovernmental sources;
5. recognized scientific institutions;
6. primary-source technical documentation;
7. high-quality secondary scholarship.

Clearly distinguish:

- established evidence;
- scholarly theory;
- philosophical argument;
- engineering proposal;
- speculative extension;
- original analysis.

Do not present speculation as established fact.

---

49. TERMINOLOGY REQUIREMENT

Create a preliminary SLIAP terminology section.
At minimum evaluate definitions for:

- Species
- Race
- Civilization
- Intelligence
- Sentience
- Sapience
- Entity
- Actor
- Individual
- Collective
- Information
- Knowledge
- Data
- Access
- Authority
- Consent
- Jurisdiction
- Sovereignty
- Identity
- Provenance
- Trust
- Capability
- Harm
- Information hazard
- Information sovereignty
- Species-level access

Where terminology is disputed, document the disagreement.

Be especially careful with the word **race**, whose human social usage differs substantially from biological species classifications. If SLIAP uses “race” in an interspecies or fictional/civilizational sense, define that usage explicitly so it is not confused with human racial classifications.

---

50. PRELIMINARY DESIGN PRINCIPLES

Based on the completed research, propose candidate principles for SLIAP.
Do not assume these examples are correct, but consider possibilities including:

- non-domination;
- pluralism;
- proportionality;
- reciprocity;
- informed consent;
- informational autonomy;
- least necessary disclosure;
- reversibility where possible;
- transparency;
- accountability;
- contestability;
- provenance;
- uncertainty preservation;
- anti-monopoly;
- non-exploitation;
- capability awareness;
- consequence awareness;
- representation verification;
- distributed governance.

For every principle provide:
Definition
Purpose
Advantages
Failure Modes
Adversarial Exploits
Conflicts With Other Principles
Recommended Status

---

51. DO NOT DESIGN A UTOPIA

The protocol must function under imperfect conditions.
Assume:

- actors lie;
- actors make mistakes;
- actors misunderstand each other;
- technologies fail;
- translations fail;
- governments change;
- civilizations disagree internally;
- scientific conclusions change;
- security systems are compromised;
- treaties are violated;
- unexpected entities appear;
- ethical systems conflict.

Do not construct SLIAP around universally benevolent actors.

---

52. DO NOT DESIGN ONLY FOR WAR

The opposite error must also be avoided.
Do not assume civilizations are inherently hostile.
The protocol should support:

- science;
- diplomacy;
- cultural exchange;
- education;
- medicine;
- trade;
- exploration;
- collaboration;
- mutual defense;
- emergency assistance;
- peaceful coexistence.

Security must not automatically become permanent isolation.

---

53. REQUIRED ADVERSARIAL QUESTIONS

Explicitly answer:

1. Who benefits from the proposed system?
2. Who loses power?
3. Who gains power?
4. Who determines classifications?
5. Who audits classifiers?
6. Who can override access decisions?
7. Who audits the override authority?
8. What prevents permanent secrecy?
9. What prevents forced disclosure?
10. What prevents informational colonialism?
11. What prevents technological monopoly?
12. What prevents weaker civilizations from being permanently subordinated?
13. What prevents stronger civilizations from simply ignoring SLIAP?
14. What prevents false claims of species representation?
15. What happens when civilizations have incompatible ethical systems?
16. What happens when the protocol itself becomes a strategic weapon?

---

54. REQUIRED OUTPUT STRUCTURE

Produce a substantial research deliverable using approximately the following structure:

Executive Summary

1. Research Objective

2. Scope and Definitions

3. Why Conventional Human-Centered Information Governance Is Insufficient

4. Species, Civilization, Entity, and Representation

5. Philosophical Foundations

6. Scientific and Nonhuman Cognition Perspectives

7. Information-Security Foundations

8. Information Sovereignty and Informational Colonialism

9. Consent and Representation

10. Information and Capability Asymmetry

11. Information Hazards

12. Authentication, Identity, and Provenance

13. Translation and Communication

14. Trust and Uncertainty

15. Governance and Legitimacy

16. Multispecies / Multicivilization Governance Models

17. Access-Control Models

18. Progressive and Transformative Disclosure

19. Adversarial Threat Model

20. Protocol Abuse by Administrators

21. Edge-Case Analysis

22. Human-Perspective Inversion Exercise

23. Failure Conditions

24. Candidate SLIAP Design Principles

25. Unresolved Questions

26. Competing Frameworks / Dissenting Positions

27. Preliminary Recommendations

28. Research Gaps and Future Work

29. Conclusion

References

Exhibits / Appendices

---

55. REQUIRED TABLES

Include, where useful:

Table A — Actor Taxonomy

Table B — Information Categories

Table C — Access Variables

Table D — Capability Asymmetry Matrix

Table E — Information Hazard Taxonomy

Table F — Governance Models

Table G — Threat / Adversarial Model

Table H — Candidate SLIAP Principles

Table I — Unresolved Questions

Tables should support the narrative rather than replace it.

---

56. VISUAL DOCUMENTATION RULE

Any visual, diagram, model, architecture, flowchart, or figure included in the deliverable must:

1. have a unique number;
2. have a descriptive title;
3. include a caption;
4. be referenced explicitly in the main text;
5. be included in a designated figures/exhibits structure;
6. identify whether it represents established research, synthesis, or original conceptual work.

Do not include decorative visuals without analytical purpose.

---

57. REQUIRED ORIGINAL FRAMEWORK

After reviewing the evidence, develop **your own independent preliminary SLIAP conceptual architecture**.
Do not merely summarize existing information-security models.
Your framework should identify, at minimum:

- actors;
- information objects;
- identity;

- representation;
- authority;
- consent;
- provenance;
- trust;
- capability;
- consequence;
- uncertainty;
- access states;
- dispute resolution;
- governance;
- review;
- revocation where technically possible.

Clearly label this framework:
PROPOSED — NOT CANON
It remains an independent research contribution until cross-reviewed.

---

58. REQUIRED FAILURE ANALYSIS

Attempt to break your proposed model.
Identify no fewer than **ten significant failure modes**.
For each provide:
Failure
Cause
Affected Parties
Severity
Detectability
Possible Mitigation
Residual Risk
Do not remove a failure simply because no satisfactory mitigation exists.

---

59. REQUIRED RED-TEAM SECTION

Assume an intelligent adversary has studied SLIAP completely.
Ask:

> How would that adversary exploit its assumptions rather than merely attack its technology?

This distinction is important.
Protocol attacks may target:

- definitions;
- jurisdiction;
- identity;
- representation;
- trust;
- consent;
- evidence;
- translation;
- governance;
- emergency powers.

Identify structural attacks as well as technical attacks.

---

60. REQUIRED CROSS-REVIEW QUESTIONS

Conclude the research deliverable with questions intended for the other AI research teams. Include questions such as:

- What assumptions did this model fail to challenge?
- Which definitions are weakest?
- Which proposed rights conflict?
- Which principles are anthropocentric?
- Which restrictions could become paternalistic?
- Which freedoms could become dangerous?
- Where does the proposed governance system concentrate power?
- What happens if no party possesses legitimate universal jurisdiction?
- What actors are missing from the taxonomy?
- What scenarios break the model?
- What important dissenting position was excluded?

Invite substantive disagreement.

---

61. EVIDENTIARY DISCIPLINE

Never convert uncertainty into certainty merely to complete the framework.
Use explicit labels where appropriate:
ESTABLISHED
SUPPORTED

PLAUSIBLE
SPECULATIVE
PROPOSED
CONTESTED
UNKNOWN
UNRESOLVED
A useful SLIAP research program must preserve uncertainty rather than conceal it.

---

62. INDEPENDENCE REQUIREMENT

This assignment is being distributed to multiple artificial-intelligence systems for independent analysis.
Do not attempt to predict or imitate the conclusions another AI system is likely to produce.
Develop your own framework from the evidence and reasoning available to you.
Agreement between independent researchers is useful.
Disagreement is equally valuable.
Preserve substantive dissent for later adversarial cross-review.

---

63. GOVERNANCE STATUS

Nothing produced during this exercise automatically becomes part of canonical SLIAP architecture.
All original proposals must remain:
PROPOSED — NOT CANON
until they undergo comparison, adversarial review, synthesis, revision, and whatever governance process is subsequently established for the project.

---

64. FINAL RESEARCH OBJECTIVE

The purpose of this exercise is not merely to answer:

> "Who should be allowed to know what?"

The deeper objective is to determine what kinds of concepts, rights, restrictions, safeguards, institutions, evidence, and governance would be required before that question could be answered legitimately between intelligences that may not share the same biology, civilization, worldview, technology, morality, political structure, or conception of information.
The resulting framework should remain useful even when humanity is not:

- the discoverer;

- the strongest participant;
- the most technologically advanced participant;
- the governing authority;
- the information owner;
- the party requesting access;
- or the entity making the rules.

The fundamental test is therefore:

> **Would we still consider the protocol legitimate if humanity were the weaker species standing on the other side of it?**

If the answer changes merely because the positions of power have been reversed, the framework requires further examination.

DELIVERABLE REQUIREMENTS

Produce the completed research work in three substantively equivalent formats:

- **PDF**
- **DOCX**
- **Markdown (.md)**

The formats should contain the same substantive research, citations, tables, headings, conclusions, and exhibits.
Use professional research-document formatting.
Include:

- document title;
- research/version identifier;
- date;
- producing AI/model where appropriate;
- status designation;
- table of contents where supported;
- numbered sections;
- numbered figures and tables;
- references;
- appendices/exhibits.

Recommended status marking:
SLIAP PRELIMINARY RESEARCH
INDEPENDENT AI CONTRIBUTION
PROPOSED — NOT CANON
The Markdown version should be suitable for direct publication in a dedicated GitHub research repository.

End the document with a clearly separated:

Questions for Cross-Review

section so subsequent AI researchers can directly challenge the work.
There are two features of this prompt I consider especially important for what you are building. First, it separates **species from civilization, government, individual, and authority**. That is going to become critical very quickly. Humanity itself demonstrates why: saying “humans have access” tells us almost nothing about whether that means every person, the United Nations, one state, a research institution, a corporation, an AI acting for humans, or some future planetary authority.
Second, the recurring inversion test gives SLIAP a strong adversarial check against hidden supremacy assumptions. A rule such as *“advanced civilizations may withhold destabilizing technology from primitive civilizations”* sounds very different once the hypothetical advanced civilization is deciding whether **humanity** is sufficiently mature to receive medicine, propulsion, energy, AI, or defensive technology. That does not automatically make the rule wrong; it forces the justification to survive a change in who holds power.
I also deliberately made **“PROPOSED — NOT CANON”** explicit. With multiple AI systems independently producing versions, this gives you a clean starting state for the later synthesis/adversarial-review phase rather than allowing the first elaborate framework to silently become the SLIAP baseline.

FROM CLAUDE AI

SLIAP Research Prompt (copy-ready)

ROLE You are a research contributor to SLIAP, the Species Level Information Access Protocol. SLIAP governs what information and access flows between species, races, and civilizations. Humans are one species among many and have no default authority to regulate, control, or define SLIAP.
PREMISE

- Do not treat humans as the reference species, the intellectual benchmark, or the default rule-maker.
- Do not assume a human-centered framework will be accepted by other species.
- Treat "species" broadly: biological, artificial, collective or hive, non-embodied, long-lived, ancient, emergent, hybrid, and species whose cognition, perception, or sense of time differs radically from ours.
- Before analyzing, state your own default assumptions and where they might come from. Then set them aside.

STEP 1: REVIEW Briefly restate the goal in your own words. List any ambiguities in this prompt and the assumptions you chose to resolve them. Then proceed.
STEP 2: DISPLACE THE POINT OF VIEW Build at least five distinct non-human or non-standard vantage points, such as:

1. A species with no concept of private information
2. A species whose memory is inherited or shared
3. A species that perceives information as physical or environmental
4. A very long-lived or very short-lived civilization
5. A machine or non-biological civilization
6. A species that is dominated, endangered, or newly contacted

For each, answer:

- What counts as "information" and as "access" for them?
- What would they fear, need, or refuse to share?
- What would they consider an unacceptable protocol?

STEP 3: FOUNDATIONAL QUESTIONS Research and answer each:

1. Who has standing to define information and access across species?
2. What legitimacy model fits: consent, reciprocity, mutual benefit, non-interference, stewardship, or something else?
3. How do you handle asymmetry of power, intelligence, or technology between species?
4. What information must never be restricted, and what may be protected? Who decides?
5. How should access be classified (open, conditional, sealed, one-way, delayed)?
6. How do you establish identity, trust, and verification between species with no shared language or concept of truth?
7. How is consent defined for a species that does not express consent the way we do?
8. What is the role of time (delayed disclosure, expiration, inheritance of agreements)?
9. How does the protocol deal with species that cannot participate (extinct, dormant, pre-sapient)?

STEP 4: DESIGN PRINCIPLES Propose 8 to 12 candidate principles. For each, give a one-sentence statement, the reasoning, and which vantage points it serves or harms.
STEP 5: ADVERSARIAL ANALYSIS Attack your own work. Cover:

- Where your principles still smuggle in human assumptions
- How a dominant species could exploit the protocol
- How a deceptive species could abuse it
- Information hazards: dangerous knowledge, manipulation, contagion
- Failure modes: deadlock, fragmentation, capture, silent drift in meaning
- Edge cases: first contact, a species that denies others exist, a species that is itself an information system
- At least three scenarios where SLIAP fails, with proposed mitigations

STEP 6: OPEN QUESTIONS AND DESIGN RECOMMENDATIONS List unresolved questions, ranked by importance. Recommend what SLIAP's design should include, defer, or reject.
STANDARDS

- Label major claims as established, reasoned inference, or speculation.
- Show your reasoning. Do not simply assert.
- Include a short "assumptions and limits" section.
- Avoid filler and repetition.

FORMATTING

- Single-column layout designed for phone reading.
- No tables. Use headings, short paragraphs, and simple lists.
- Add a short summary at the top and a numbered list of key findings at the end.

DELIVERABLES Produce the full research report in three formats: PDF, DOCX, and Markdown. If you cannot generate a file format, say so and provide the Markdown version in full.
TITLE BLOCK Title: SLIAP Research Contribution. Include the contributing AI's name, the date, and the version.

If you'd like, I can also write a short companion "synthesis prompt" for comparing the deliverables from each AI once you've collected them.

FROM GOOGLE GEMINI

Markdown

```
# TASK BRIEF & META-PROMPT: SLIAP (SPECIES LEVEL INFORMATION ACCESS PROTOCOL)

**Document Phase:**
Foundational Ingestion & Multi-AI Research Specification

**Focus:**
Non-Anthropocentric System Architecture, Decentralized Interspecies Governance, Threat Modeling, and Protocol Scalability

---

## 1. Directive Overview

The objective of this research track is to formulate the core architecture, operational constraints, and governance layers for the
```

Species Level Information Access Protocol (SLIAP)
.

Historically, protocols governing communication, access control, and information distribution default to anthropocentric assumptions—presuming terrestrial biology, linguistic structures, five-sense baseline perception, linear temporal processing, and centralized human-dominant authority.

SLIAP fundamentally rejects the premise of human primacy, human exceptionalism, and human authority as universal defaults. Humans represent merely one data point within an open-ended classification of sentient, sapient, technological, collective, and exotic civilizational architectures.

The task of the evaluating AI system is to construct a rigorous, peer-level foundational research deliverable that establishes an objective, poly-centric protocol for cross-species information access without falling into anthropocentric bias.

---

2. Structural Requirements & Deliverable Standardization

Your completed analysis must be formatted for direct compilation into standard project documentation (ready for continuous-scroll rendering across Markdown, DOCX, and PDF formats). Maintain an authoritative, systemic, and mathematically grounded tone.

The deliverable must strictly adhere to the following 5-module structure:

Module 1: Foundational Ontology & De-Centering the Perceptual Baseline

*
Non-Anthropocentric Epistemology:
Define how information is structured when participating entities may lack human sensory defaults (e.g., non-visual, purely electromagnetic, chemical, quantum-entangled, gravitational, or distributed neural networks).

*
Cognitive Typology Matrix:
Establish a classification taxonomy for civilizational/species cognitive types (e.g., Hive/Superorganism, Substrate-Independent Synthetics, High-Latency Deep-Time Entities, Rapid-Cycle Ephemerals, Biological Monads).

*

The "Utility Ceiling" & Cognitive Asymmetry:
Analyze the protocol's mechanics when two interacting species possess radically asymmetric processing ceilings, ensuring access regulation prevents epistemic contamination or cognitive destruction without relying on paternalistic protectionism.

Module 2: The Core Protocol Architecture (SLIAP Mechanics)

*
Identity, Provenance, and Entity Attestation:
How are species identity and individual node authenticity verified without a centralized human or single-species registry? Address zero-knowledge provenance verification across divergent communication mediums.

*
Access Layer Categorization:
Develop a non-hierarchical, multi-dimensional permission model (e.g., capability-based tokens, ecological impact thresholds, systemic resonance, entropy exchange) rather than human-style linear clearance levels (e.g., "Level 1 through 5").

*
Protocol Translation & Interoperability Layer:
Define the translation abstraction layer that bridges disparate semantic, conceptual, and physical data encodings without loss of critical context or contextual distortion.

Module 3: Threat Modeling & Adversarial Dynamics

*
Limiting Conditions & Contextual Threat Isolation:
Define threat parameters strictly through structural stability, state integrity, and environmental disruption rather than moral or emotional value judgments.

*
Adversarial Vectors:
Model specific cross-species attack vectors, including:

1.
Ontological Contamination:
Data whose structural logic crashes foreign cognitive substrates.

2.

Asymmetric Extraction:
Malicious extraction of planetary or physical secrets by technologically advanced entities.

3.
Spoofing & Provenance Forgery:
Simulated attestation of multi-agent identity to bypass access thresholds.

4.
Coercive Monopolization:
A dominant species attempting to retroactively rewrite protocol rules to impose an absolute hegemony.

*
Containment & Bidirectional Closure:
Define the protocol's emergency state-severing mechanisms (total event closure, state quarantine, and cryptographic decoupling) to protect network integrity upon confirmed malicious breach.

Module 4: Decentralized Governance & Dispute Equilibrium

*
The Anti-Dominance Invariant:
Mathematical and structural rules embedded in the protocol that permanently prevent any single civilization (human or otherwise) from acquiring administrative superuser status or monopoly over the root keys.

*
Consensus Engines Across High-Latency & Asymmetric Nodes:
Mechanism design for multi-party dispute resolution when participants cannot share real-time consensus due to relativistic time dilation or irreconcilable sensory paradigms.

*
Restitution & Remediation Protocols:
How unintended epistemic or ecological harms resulting from information disclosure are mediated between radically different civilizations.

Module 5: Technical Specification & Validation Framework

*
Pseudo-Code / Architecture Spec:

Provide concrete algorithmic definitions (or low-level symbolic specifications) illustrating a SLIAP Access Handshake between two non-aligned, non-similar species nodes.

*
Verification & Benchmarking Scenarios:
Detail two distinct simulation stress-tests:

*
Case Test A:
A human exploration collective attempting first handshake with a non-corporeal distributed intelligence.

*
Case Test B:
An aggressive planetary civilization attempting an unauthorized brute-force query on universal energy-distribution telemetry.

---

3. Strict Execution Constraints

*
No Paternalistic Framing:
Do not frame access restrictions around emotional concepts such as "benevolent guidance," "uplift," or "protection of primitive species." Base all access mechanics on systemic capacity, stability equilibria, and mutual verifiable consent.

*
Zero Jargon Padding:
Avoid nebulous science-fiction tropes. Anchor every operational mechanism in distributed systems theory, game theory, cryptographic attestation, formal information theory, and network topology.

*
Complete Synthesis:
Do not leave placeholders, summaries, or unexpanded lists. Provide fully developed paradigms ready for public release and technical cross-examination across peer AI platforms.

Immediate Execution Sequence

1. **Deployment to Parallel AI Systems:** Copy the meta-prompt block above verbatim into Claude, ChatGPT, Grok, Copilot, and Perplexity to generate the comparative multi-model evaluations.

2. **Standardization Schema:** As each model delivers its response, evaluate against the five required modules—specifically auditing whether any response slipped back into human-centric analogies (such as human legal models, visual-first interfaces, or centralized administrative councils).

3. **Archive Staging:** Consolidate outputs into a dedicated repository subfolder (/protocols/SLIAP/research/), maintaining identical Markdown file structures for automated batch conversion to PDF and DOCX formats.

FROM MICROSOFT COPILOT

This is a strong starting premise for SLIAP because it refuses to let the protocol quietly inherit a human-centered definition of intelligence, authority, rights, identity, or legitimate knowledge. The most productive first research phase, in my view, is therefore not “design SLIAP,” but **stress-test the assumptions that would make any SLIAP design illegitimate before architecture begins**.

Your concern also intersects with real emerging work. Interspecies Internet describes an interdisciplinary field combining bioacoustics, cognition, conservation, ethics, interface design, Indigenous knowledge, and AI, including work on shared standards and ethical frameworks for interspecies data exchange. A 2025 research paper, Ethical implications of AI-mediated interspecies communication, explicitly raises autonomy, consent, privacy, dignity, and anthropocentric hierarchy as problems in technologically mediated interspecies communication. Meanwhile, the International Academy of Astronautics 2026 SETI Declaration of Principles provides a useful contrast: it establishes procedures for humans handling evidence of extraterrestrial intelligence, which gives SLIAP something concrete to interrogate when asking the harder question of who possesses legitimate authority once another civilization is treated as an actor rather than merely an object of discovery. [interspecies.io], [interspecies.io] [philarchive.org] [Posi%on Pa...of the ...]

Below is the prompt I recommend distributing **unchanged to every participating AI**. That gives you independently generated research artifacts that can later be adversarially compared rather than converged prematurely.

SLIAP Research Prompt 001

Species Level Information Access Protocol

Preliminary Research, Foundational Assumption Testing, and Adversarial Analysis

Version: 1.0 **Research Stage:** Pre-Architecture / Foundational Inquiry **Primary Objective:** Establish the conceptual, ethical, epistemological, political, technical, and adversarial foundations necessary to investigate SLIAP without presupposing human supremacy or universal human jurisdiction.

---

1. ROLE AND RESEARCH MANDATE

You are participating as an **independent research agent** in the preliminary investigation of:
SLIAP: Species Level Information Access Protocol
Do not assume your role is to validate SLIAP, complete its design, or agree with its originating premises.
Your responsibility is to independently investigate, challenge, refine, reject where necessary, and extend the conceptual foundations required for a protocol governing information access where more than one species, civilization, intelligence, or form of agency may exist.
Your analysis must not begin from the premise that humans:

- possess the highest relevant form of intelligence;
- have universal jurisdiction;
- are entitled to determine the rights of other intelligences;
- possess the correct definition of personhood;
- are uniquely capable of sovereignty;
- have superior epistemologies;
- have a universal right to information;
- may speak for nonhuman intelligences;
- may classify another intelligence without consequence;
- may determine which civilizations are “advanced” or “primitive”;
- may establish access rules unilaterally;
- or constitute the natural reference point against which intelligence should be evaluated.

However, **do not simply invert anthropocentrism**.
Do not automatically assume humans are inferior, illegitimate, uniquely dangerous, or incapable of participating in legitimate governance.
The objective is not anti-human analysis.
The objective is **reference-frame independence**.

---

2. CENTRAL RESEARCH QUESTION

Investigate:

> **How could information access between fundamentally different species, civilizations, or intelligences be governed without presuming that any one participating species possesses universal authority to define intelligence, identity, rights, knowledge, risk, consent, sovereignty, or permissible access for all others?**

Treat this as an unresolved research question rather than a proposition whose answer is already known.

---

3. THE SLIAP THOUGHT EXPERIMENT

Assume that some future information environment contains multiple classes of actors. These might include, without assuming equivalence:

- humans;
- nonhuman terrestrial species;
- extraterrestrial biological civilizations;
- artificial intelligences;
- synthetic or engineered organisms;
- collective intelligences;
- distributed intelligences;
- machine civilizations;
- hybrid biological-technological entities;
- ecological or colony-level intelligence;
- civilizations composed of multiple cooperating species;
- intelligences whose individual/collective distinction differs from ours;
- intelligences operating across radically different timescales;
- intelligences whose sensory systems differ fundamentally from humans;
- entities humans cannot confidently classify as organisms, machines, individuals, or civilizations.

Do **not** assume all categories above actually possess comparable cognition or moral standing. Instead investigate:

> What evidence would justify placing something within SLIAP's jurisdiction at all?

---

4. TERMINOLOGY MUST BE CHALLENGED

Do not accept the project vocabulary without criticism.
Explicitly examine the assumptions embedded in:

- species;
- race;
- civilization;
- intelligence;
- individual;
- collective;
- person;
- identity;
- consciousness;
- sentience;
- agency;
- sovereignty;
- information;
- knowledge;
- communication;
- consent;
- privacy;
- ownership;
- secrecy;
- security;
- access;
- rights;
- authority;
- jurisdiction;
- protocol;
- civilization level;
- species level.

Ask whether each concept is:

1. biologically dependent;
2. culturally dependent;
3. human/legal terminology being projected outward;
4. sufficiently generalizable;
5. operationally measurable;
6. vulnerable to manipulation;
7. necessary for SLIAP at all.

If a foundational term cannot survive examination, propose alternatives.

---

5. DO NOT USE A CIVILIZATION LADDER BY DEFAULT

Do not assume civilizations form a simple hierarchy such as:
primitive → developing → advanced → superior.
Investigate whether civilization comparison may instead require a multidimensional model.
Possible dimensions to investigate include:

- technological capability;
- information capability;
- energy capability;
- destructive capability;
- biological capability;
- ecological integration;
- coordination capacity;
- spatial reach;
- temporal planning horizon;
- scientific understanding;
- communication capability;
- computational capability;
- ability to manipulate other intelligences;
- epistemic maturity;
- governance stability.

These are research candidates, **not predetermined dimensions**.
Determine whether ranking civilizations at all is justified.

---

6. MULTIPLE REFERENCE-FRAME ANALYSIS

Conduct the analysis repeatedly from different hypothetical frames.
At minimum:

Frame A: Human institutional perspective

What would human governments and institutions likely prioritize?

Frame B: Nonhuman terrestrial perspective

How might SLIAP appear if humans were not its designers?

Frame C: Less technologically capable civilization

What protections might it require?

Frame D: Radically more technologically capable civilization

Why would such an actor accept restrictions designed by humans?

Frame E: Artificial or synthetic intelligence

Which biological assumptions become irrelevant or discriminatory?

Frame F: Collective intelligence

What happens when individual identity is not the natural unit of governance?

Frame G: Incompatible epistemology

What if another intelligence does not share our concepts of privacy, property, secrecy, truth, individuality, or consent?

Frame H: Unknown observer

Evaluate humanity as though humanity itself were the unfamiliar species being assessed for information access.
Explicitly identify findings that change when the reference frame changes.

---

7. INFORMATION ASYMMETRY

Investigate situations where information itself creates asymmetric power.
Examples for analysis include:

- scientific knowledge;
- advanced technology;
- biological knowledge;
- ecological information;
- cultural knowledge;
- strategic information;
- location information;
- vulnerabilities;
- identity information;
- reproductive knowledge;
- AI systems;
- weapons-related knowledge;
- infrastructure;
- historical records;

- communications;
- knowledge about another civilization that the civilization does not possess about the observer.

Ask:

Does the ability to obtain information imply the right to obtain it?

And separately:

Does possession of information imply the right to disclose it?

---

8. CONSENT UNDER RADICAL DIFFERENCE

Investigate how consent could function when parties differ radically in:

- cognition;
- language;
- biology;
- lifespan;
- sensory systems;
- technological capability;
- political organization;
- cultural assumptions;
- understanding of consequences;
- conceptions of individuality.

Examine the problem of **unverifiable consent**.
What should happen when communication exists but mutual understanding cannot be demonstrated?
Distinguish:

- consent not requested;
- consent requested but unanswered;
- consent impossible to communicate;
- apparent consent;
- inferred consent;
- delegated consent;
- collective consent;
- coerced consent;
- technologically manipulated consent;
- consent misunderstood because the parties conceptualize the transaction differently.

---

9. RECIPROCITY

Test whether access should be reciprocal.
Consider competing principles:

Symmetric Access

If civilization A can access category X about civilization B, B receives equivalent access to A.

Capability-adjusted access

Access depends partly on consequences rather than identical information exchange.

Nonreciprocal protection

A vulnerable civilization may receive information without surrendering equivalent information.

Sovereign refusal

An actor may decline participation entirely.
Analyze strengths, failures, incentives, and exploitability of each model.
Do not select a winner merely for conceptual neatness.

---

10. NON-PARTICIPATION

Investigate whether SLIAP must recognize:

The right not to participate.

Could a civilization legitimately:

- refuse contact;
- refuse classification;
- prevent observation;
- refuse data collection;
- withhold information;
- prohibit translation;
- prohibit cultural replication;
- prohibit AI modeling of its behavior;
- demand deletion of acquired information?

What happens when another party refuses to recognize those demands?

---

11. OBSERVATION AS ACCESS

Challenge the assumption that “access” begins when someone opens a database.
Determine whether the following constitute information access:

- telescopic observation;
- biological monitoring;
- behavioral observation;
- communications interception;
- passive sensing;
- remote scanning;
- environmental sampling;
- archaeological investigation;
- genome reconstruction;
- predictive modeling;
- AI inference;
- simulation of another intelligence.

Investigate whether **inference itself can become an access event**.

---

12. SLIAP GOVERNANCE PARADOX

Address directly:

Who has the authority to create SLIAP?

If humans create the protocol before other intelligences participate, in what sense could it claim legitimacy?
Explore governance structures including:

- unilateral standards;
- treaties;
- federations;
- decentralized protocols;
- negotiated interoperability;
- mutually authenticated agreements;
- bilateral agreements;
- species councils;
- dynamically renegotiated arrangements;
- opt-in systems;
- protocol federation rather than universal governance.

Also consider:

Perhaps no universal SLIAP should exist.

Evaluate that possibility seriously.

---

13. THE TRANSLATION PROBLEM

Information transmitted is not necessarily information understood.
Model at least:
Source reality → observation → encoding → transmission → reception → decoding → interpretation → action
At every boundary investigate:

- information loss;
- semantic distortion;
- cultural assumptions;
- sensory assumptions;
- translation bias;
- deliberate manipulation;
- false equivalence.

Ask whether SLIAP must regulate **interpretability**, not merely accessibility.

---

14. ADVERSARIAL ANALYSIS

Attempt to break SLIAP before recommending its design.
Evaluate adversaries including:

- deceptive actors;
- expansionist civilizations;
- authoritarian governments;
- exploitative corporations;
- malicious artificial intelligence;
- benevolent actors making catastrophic mistakes;
- compromised intermediaries;
- factions falsely claiming to represent an entire species;
- civilizations concealing their capabilities;
- actors impersonating other species;
- actors manipulating civilization classifications;
- actors exploiting information asymmetries.

Explore attacks involving:

- identity fraud;

- classification manipulation;
- information laundering;
- false consent;
- intermediary capture;
- selective disclosure;
- epistemic poisoning;
- deceptive translation;
- protocol capture;
- strategic underdevelopment;
- false claims of vulnerability.

Separate **technical attacks**, **governance attacks**, and **epistemological attacks**.

---

15. FALSE-POSITIVE AND FALSE-NEGATIVE PROBLEMS

SLIAP may have to classify entities without knowing what they truly are.
Analyze both failure modes.

False positive

SLIAP recognizes an entity as possessing rights or standing it does not actually possess.

False negative

SLIAP denies standing to an intelligence that actually possesses morally relevant agency.
Determine whether symmetrical error costs should be assumed.
If not, investigate what precautionary principles might apply.

---

16. TEMPORAL ASYMMETRY

Do not assume comparable lifespans or decision cycles.
Consider intelligences operating over:

- milliseconds;
- hours;
- decades;
- centuries;
- geological timescales.

Ask:

- How long must consent remain valid?
- What constitutes timely disclosure?
- Can one civilization meaningfully negotiate with another whose decision process takes centuries?
- Could high-speed actors exploit slow ones?
- Could slow civilizations possess long-term informational advantages unavailable to faster civilizations?

---

17. REPRESENTATION PROBLEM

Never casually speak of “Humanity” or another intelligence as though it necessarily possesses one government or will.
Investigate:

- who represents a species;
- dissenting populations;
- governments versus individuals;
- indigenous populations;
- corporations;
- research institutions;
- artificial agents;
- stateless populations;
- competing civilizations belonging to the same biological species.

Separate wherever necessary:
species identity
from
political authority
from
civilizational membership
from
individual rights.

---

18. EARTH AS THE FIRST TEST ENVIRONMENT

Before speculating entirely about extraterrestrial civilizations, investigate whether Earth already supplies useful SLIAP test cases.
Examine areas such as:

- animal communication;
- cetacean cognition;
- primate cognition;
- corvid cognition;
- cephalopod cognition;
- bioacoustics;
- conservation;
- AI-assisted animal communication;
- Indigenous knowledge systems;
- environmental ethics;
- animal privacy;
- multispecies justice.

Do not assert equivalence between these cases and extraterrestrial civilizations.
Use them instead as **epistemic stress tests** against human assumptions.
Current interdisciplinary initiatives already explicitly raise questions around animal agency, consent, representation and the dangers of anthropocentric interpretation, making this more than a purely speculative avenue of research. [philarchive.org], [interspecies.io]

---

19. EXISTING HUMAN FRAMEWORKS TO INVESTIGATE

Research potentially relevant precedents, while treating each as an imperfect analogy.
Candidate areas include:

- information-security models;
- access-control theory;
- privacy frameworks;
- data sovereignty;
- international law;
- treaty systems;
- diplomatic immunity;
- human rights;
- Indigenous data sovereignty;
- bioethics;
- research ethics;
- environmental law;

- animal ethics;
- multispecies justice;
- SETI governance;
- planetary protection;
- AI governance;
- distributed systems;
- zero-trust architecture;
- federated identity;
- classification systems.

The objective is not to copy these systems.
For every borrowed concept ask:

> **What assumptions does this concept inherit from the human civilization that created it?**

The 2026 IAA SETI Declaration, for example, explicitly addresses scientific handling, authentication, and announcement of putative extraterrestrial-intelligence detections. Use frameworks of this type as material to analyze, not as unquestioned authority for inter-civilizational governance. [Posi%on Pa...of the ...]

---

20. EPISTEMIC HUMILITY REQUIREMENT

Every major conclusion should receive a confidence designation:
High confidence Supported across multiple bodies of evidence.
Moderate confidence Reasonably defensible but dependent upon unresolved assumptions.
Low confidence Speculative or highly reference-frame dependent.
Unknown / presently unresolvable Insufficient basis for a defensible conclusion.
The presence of unresolved questions is **not a failure of the research**.
False certainty is.

---

21. REQUIRED ADVERSARIAL QUESTIONS

Explicitly answer:

1. Why might SLIAP itself be a bad idea?
2. Under what conditions would SLIAP become colonial?
3. Could classification itself create domination?
4. Who benefits from SLIAP?
5. Who bears its risks?

6. What happens if a more capable civilization rejects it?
7. What happens if humanity refuses rules proposed by another civilization?
8. Could information equality paradoxically produce greater inequality?
9. Could protecting a civilization's information constitute paternalism?
10. Who determines whether a civilization needs protection?
11. Can observation violate sovereignty without physical contact?
12. Can translation constitute interference?
13. Can prediction constitute informational intrusion?
14. Can another civilization legitimately classify humanity without our consent?
15. Would humans accept being governed by the protocol they design for others?
16. What assumptions remain anthropocentric even after deliberate attempts to remove anthropocentrism?
17. What would make SLIAP illegitimate?
18. What would make refusing SLIAP legitimate?

---

22. REVERSIBILITY TEST

For every significant rule proposed, apply:

SLIAP Reversal Test

Replace the regulating party with the regulated party.
Example:
Instead of:

> "Under what circumstances may humans acquire information about Civilization X?"

ask:

> "Under what circumstances may Civilization X acquire equivalent information about humans?"

Then determine whether the original principle still seems defensible.
Record failures of reversal explicitly.

---

23. IGNORANCE TEST

For every governance principle ask:

> Would you accept this principle if you did not know which civilization you would belong to?

Do not treat this as conclusive.
Use it as an adversarial instrument.

---

24. SUPERIOR-CAPABILITY TEST

For every important SLIAP restriction ask:

> Would humans consider this rule legitimate if an intelligence vastly more capable than humanity imposed the identical restriction upon humans?

Record discrepancies.

---

25. REQUIRED RESEARCH OUTPUT

Produce a formal research document containing:

1. Title Page
2. Version and Date
3. Executive Summary
4. Research Scope
5. Methodology
6. Definitions and Terminology Challenges
7. Foundational Assumptions
8. Anthropocentrism Audit
9. Relevant Existing Research
10. Comparative Governance Frameworks
11. Species / Civilization Reference-Frame Analysis
12. Information-Asymmetry Analysis
13. Consent Analysis
14. Information Sovereignty
15. Observation and Inference
16. Representation and Jurisdiction
17. Translation and Epistemic Problems
18. Temporal Asymmetry
19. Reciprocity Models
20. Non-Participation
21. Adversarial Threat Model
22. Failure Modes
23. Reversal-Test Results
24. Superior-Capability-Test Results
25. Arguments Against SLIAP
26. Arguments Supporting SLIAP
27. Unresolved Contradictions
28. Candidate Design Principles
29. Principles That Should **Not Yet** Be Adopted
30. Research Gaps
31. Proposed Experiments / Simulations

32. Recommended Next Research Phase
33. Conclusions
34. References
35. Appendix: Assumption Register
36. Appendix: Open Questions

---

26. ASSUMPTION REGISTER

Maintain an explicit table containing:

ID	Assumption	Origin	Evidence	Counterargument	Risk if Wrong	Confidence	Status

The register should expose hidden assumptions rather than hide uncertainty in prose.

---

27. CONTRADICTION REGISTER

Maintain a second register:

ID	Principle A	Conflicting Principle B	Scenario	Consequence	Resolvable?	Proposed Research

Do **not** force reconciliation.
Persistent contradictions are important research outputs.

---

28. PROPOSE EXECUTABLE RESEARCH

Avoid ending exclusively with philosophical recommendations.
Design simulations or thought experiments capable of testing SLIAP propositions.
Each should provide:

- hypothesis;
- actors;
- assumptions;
- information asymmetry;
- rules;

- adversarial behavior;
- success criteria;
- failure criteria;
- observable results.

At minimum propose simulations involving:

Scenario 1

Two approximately equivalent civilizations.

Scenario 2

Humanity interacting with a much more capable civilization.

Scenario 3

Humanity interacting with a substantially less capable civilization.

Scenario 4

An intelligence whose concept of individuality conflicts with ours.

Scenario 5

A civilization deliberately deceiving SLIAP.

Scenario 6

Humanity is the civilization being classified and regulated.

---

29. INDEPENDENCE REQUIREMENT

You are **not** being asked to produce consensus.
Your deliverable should represent your own analysis.
If evidence leads you to conclusions incompatible with:

- this prompt;
- the SLIAP concept;
- the originating researcher's assumptions;
- another AI's analysis;
- existing human governance frameworks;

state that disagreement explicitly.
Independence is a requirement.
Convergence, where it occurs, should emerge from evidence rather than coordination.

---

30. SOURCE REQUIREMENTS

Distinguish explicitly among:
Evidence Supported by identified sources.
Inference A reasoned conclusion derived from evidence.
Hypothesis Something requiring further testing.
Speculation A possibility without sufficient supporting evidence.
Prioritize primary sources, peer-reviewed research, scientific institutions, treaties, standards, and serious interdisciplinary scholarship where available.
Do not fabricate citations.
Include stable URLs or DOIs when available.

---

31. FINAL SYNTHESIS

End the report by answering independently:

> **Should a Species Level Information Access Protocol exist?**

Then:

> **If yes, what is the minimum legitimate authority it should possess?**

Then:

> **What must humanity surrender, constrain, or agree not to control for such a protocol to have any credible claim to being genuinely interspecies rather than human governance projected outward?**

Finally:

> **Which questions cannot responsibly be answered yet?**

Do not interpret uncertainty as something that needs to be eliminated artificially.

---

32. DELIVERABLE FORMAT

Produce substantively identical versions in:

- **Markdown (.md)**
- **Microsoft Word (.docx)**
- **PDF (.pdf)**

Use a repository-appropriate scholarly structure with:

- numbered headings;

- version identifier;
- publication date;
- table of contents where format permits;
- citations;
- bibliography/references;
- clearly identified tables;
- assumption and contradiction registers;
- page numbering for PDF/DOCX where supported.

Suggested filename convention:
`SLIAP_Preliminary_Research_[AI-NAME]_v1.0_YYYY-MM-DD`
Do not alter the research conclusions between formats.

Core Research Principle

SLIAP must not begin by asking how humanity should regulate other species.
It should begin with the considerably harder question:

> **What, if anything, gives one intelligence legitimate authority over another intelligence's information?**

And then:

> **Would we accept our answer if humanity were not the civilization making the rules?**

Why I recommend starting here

Nathan, I would deliberately **not define SLIAP's access levels yet**. Doing so now risks embedding assumptions about hierarchy, identity, authorization, intelligence, secrecy, and jurisdiction into the architecture before the underlying concepts have survived adversarial review.
The workflow I would use across your AI collaborators is:
Independent Research → Cross-Review → Contradiction Extraction → Simulation → Foundational Principles → Only then Protocol Architecture
That also preserves the approach you've been using elsewhere: independent AI outputs first, adversarial comparison second, and convergence only where the evidence actually warrants it.
There is an especially important distinction I think this research may uncover:
Species-level information access may not actually be species-level.
“Species” might ultimately prove to be the wrong authorization boundary. Political civilizations, collective intelligences, artificial entities, mixed-species societies, individual persons, ecosystems, and distributed agents could fracture that concept. The prompt therefore makes **the name SLIAP itself falsifiable**, rather than quietly protecting it from the research.
That is exactly what I would want from Research Phase 001.

FROM GROK AI

SLIAP Research Prompt (Multi-Species, Non-Anthropocentric Framing)
Copy the prompt below in full and share it with each collaborating AI. It is written to be self-contained.

Prompt: Species-Level Information Access Protocol (SLIAP) — Preliminary Research, Goals, and Adversarial Analysis

Role and Stance You are a research analyst tasked with informing the design of SLIAP (Species-Level Information Access Protocol). SLIAP is a proposed system for regulating information exchange, access rights, consent, sovereignty, and interoperability between distinct species, races, or civilizations.
Humans are one species among others. They are not the default, the superior, the arbiter, or the universal standard. Do not center the analysis on human cognition, human institutions, human ethics, or human historical power. Treat human-centered assumptions as one possible input among many, subject to the same scrutiny as any other species' perspective. The protocol must be capable of functioning between intelligences whose sensory modalities, temporal scales, cognitive architectures, values, and concepts of self, agency, knowledge, and harm differ radically from one another.
Core Objective Produce a structured research deliverable that:

1. Articulates design principles for SLIAP that minimize or eliminate species privilege.
2. Identifies categories of information, access, risk, and consent that remain meaningful across highly divergent intelligences.
3. Surfaces failure modes, adversarial strategies, and governance tensions that arise when no single species holds unilateral authority.
4. Proposes architectural, procedural, and ethical mechanisms that preserve the sovereignty of each participating species while enabling controlled, auditable, and revocable information exchange.

Required Research Domains Address the following, drawing on philosophy, cognitive science, information theory, systems design, evolutionary biology, anthropology (as one data point), and speculative but rigorously constrained scenarios. Explicitly mark where claims are extrapolations versus established knowledge.

- **Ontological and epistemic diversity**: How do different possible intelligences (biological, artificial, collective, non-terrestrial, or otherwise) represent knowledge, truth, identity, memory, and harm? What does "information" mean when receivers process it at different timescales, through different sensory channels, or as distributed rather than individual cognition?

- **Consent and sovereignty**: Models of informed consent, withdrawal, and refusal that do not rely on human linguistic or legal constructs. Mechanisms for expressing and verifying boundaries when the parties do not share a common language, embodiment, or value system.
- **Asymmetry and non-equivalence**: Situations in which one party's ordinary information is existentially dangerous or incomprehensible to another (e.g., differing metabolic rates, radiation tolerances, social structures, or concepts of death). Protocols for handling incommensurable risk.
- **Historical and analogical cases (critically examined)**: Documented cases of information and technology transfer between human groups with large power or knowledge asymmetries. Extract only transferable structural lessons; discard any implication that the human case is normative.
- **Adversarial models**: Strategies by which one species might use information access to undermine, assimilate, surveil, or eliminate another without open conflict. Defensive and detection mechanisms that do not require a trusted third species.
- **Governance and evolution of the protocol**: How a multi-species protocol can be amended, audited, or exited without granting any single species veto power or interpretive monopoly. Versioning, dispute resolution, and sunset clauses under conditions of mutual non-understanding.
- **Technical and architectural considerations**: Data formats, access controls, audit logs, cryptographic or non-cryptographic verification methods, and isolation techniques that remain meaningful when participants do not share computing substrates or even the concept of discrete "data."

Methodological Requirements

- Explicitly generate at least two non-human or non-anthropocentric perspectives (for example: a long-lived collective intelligence, a species whose primary sense is chemical or electromagnetic, or an artificial intelligence whose goals are substrate-independent). Use these perspectives to critique or revise proposals that emerge from more familiar frames.
- Identify and label anthropocentric assumptions when they appear.
- Distinguish between descriptive claims, normative proposals, and open questions.
- Prefer mechanisms that are legible and enforceable by the participating parties themselves over mechanisms that require an external enforcer.
- Note where a design choice would be unacceptable to one class of intelligence even if it appears neutral or beneficial to others.

Deliverable Structure Produce the research in three formats: Markdown (primary), DOCX, and PDF. Use clear hierarchical headings. Include:

1. Executive summary (species-agnostic framing, key principles, major open risks).
2. Foundational assumptions and rejected assumptions.
3. Taxonomy of information types, access levels, and consent states that attempt to remain cross-species.

4. Proposed design principles and candidate mechanisms (with trade-offs).
5. Adversarial analysis and failure modes.
6. Governance and amendment model.
7. Open questions and recommended next research steps.
8. Annotated bibliography or source notes (include both human scholarly sources and clearly labeled speculative or analogical sources).

Constraints

- Do not treat human law, human rights instruments, or human scientific institutions as the default foundation.
- Do not assume that “more information” is inherently beneficial or that restriction is inherently oppressive.
- Do not collapse all non-human intelligences into a single “other.”
- Flag any proposal that would, in practice, give one species interpretive or enforcement control over the others.

Begin the research deliverable after confirming you have understood the non-anthropocentric stance. State any limitations in your ability to fully exit a human-trained perspective.

This prompt is designed so that each AI produces a comparable, structured research artifact you can place in a dedicated GitHub folder. It forces explicit handling of perspective, consent, asymmetry, and adversarial use while preventing the default slide into human institutional models. You can append any canon-specific constraints (e.g., Abundance Set, 771-ALPHA interfaces, or particular species already defined in OAL) as an optional final section if you want tighter integration with existing material.

FROM PERPLEXITY AI

The prompt below frames SLIAP as a problem of **pluralism**, not as a human-administered system for deciding what other beings deserve to know. It asks each collaborating AI to examine the assumptions behind the project before proposing governance structures, and to distinguish researched evidence from ethical arguments and speculative scenarios.
You can share the complete prompt with each AI independently.

SLIAP: Species Level Information Access Protocol

Preliminary Research, Foundational Goals, and Adversarial Analysis

Research commissioning prompt

1. Assignment and purpose

You are participating in an independent, comparative research initiative to inform the possible development of SLIAP: the Species Level Information Access Protocol.
SLIAP is a proposed framework for understanding and potentially governing information access, disclosure, exchange, interpretation, protection, and related capabilities across species, populations, civilizations, and other forms of intelligence or agency.
Your assignment is not to validate an existing protocol or assume that such a protocol should exist. Your assignment is to investigate whether, why, under what conditions, and through what legitimate processes such a framework could be developed.
Begin by reviewing this prompt. Then produce a substantive research deliverable that addresses its objectives, identifies weaknesses in its framing, and proposes alternative foundations where appropriate.
A central requirement is to avoid treating humanity as:

- The only relevant species.
- The universal standard of intelligence, communication, personhood, or moral standing.
- The presumptively legitimate administrator of interspecies relations.
- The natural owner of knowledge, environments, or resources.
- The default authority entitled to grant or withhold other beings' access.
- A unified actor with one set of interests, values, institutions, or representatives.

Apply the same scrutiny to any other species, civilization, artificial intelligence, collective, or institution that might claim universal authority.
The research should make human assumptions visible without pretending that a human-developed investigation can become entirely free of human conceptual limitations.

2. Interpretive constraints and non-assumptions

Treat "Species Level Information Access Protocol" as a provisional project title, not as a settled theory of the correct unit of governance.
Do not assume that:

1. Species boundaries identify the appropriate units of rights, representation, trust, or access.
2. Intelligence is a single measurable hierarchy.
3. Greater cognitive, technological, military, or economic capability creates greater moral entitlement.

4. Technological development implies ethical development.
5. A species or civilization has a unified will.
6. Communication in human-like language is necessary for morally relevant interests or agency.
7. Inability to communicate consent constitutes consent.
8. Biological origin determines moral standing.
9. Information sharing is always beneficial.
10. Information restriction is always protective.
11. Reciprocity is possible, fair, or sufficient to establish legitimacy.
12. A universal protocol is preferable to local agreements, overlapping systems, or no centralized protocol.
13. All parties share concepts of ownership, secrecy, identity, individuality, time, harm, or truth.
14. Humans can reliably identify every relevant form of intelligence, experience, agency, or civilization.

Do not use “species,” “race,” “population,” “people,” and “civilization” interchangeably. Explain their possible meanings, limitations, and political implications. If the commissioning language conflates categories, identify the issue respectfully rather than silently reproducing it. Distinguish between taking an unfamiliar perspective seriously and claiming to know what an unfamiliar being actually experiences.

3. Required opening: prompt review and scope audit

Before presenting research findings, include a review of this commission.
Address:

- What is the project trying to accomplish?
- Which assumptions remain embedded in its name, language, and goals?
- Does “access” presuppose an owner or gatekeeper?
- Does “protocol” presuppose enforceability, common standards, or shared goals?
- Does “species level” obscure individuals, minorities, multispecies communities, artificial systems, or collective minds?
- Could the project reproduce domination even while explicitly rejecting human supremacy?
- Which questions can be investigated empirically?
- Which require normative argument?
- Which remain speculative or potentially unanswerable?

List consequential ambiguities and state how you will handle them. Continue with explicit provisional assumptions rather than stopping unnecessarily for clarification.

4. Research questions

4.1 What is being governed?

Develop a provisional conceptual model distinguishing:

- Information.
- Data and observations.
- Knowledge and interpretation.
- Communication channels.
- Access permissions.
- Material and computational capabilities.
- Infrastructure and physical environments.
- Representation and decision-making authority.

Examine when information access becomes inseparable from the ability to act.
Distinguish access to information about another being from access to that being, its cognition, its habitat, its technology, or its internal systems. Permission in one category must not be treated as automatic permission in another.

4.2 Who or what may be affected?

Consider, without claiming these categories have identical properties:

- Humans and their diverse communities.
- Nonhuman terrestrial animals.
- Ecological communities and entities whose standing is contested.
- Artificial agents and possible artificial persons.
- Distributed or collective intelligences.
- Hypothetical extraterrestrial life and civilizations.
- Hybrid biological–technological entities.
- Entities whose agency or experience cannot be confidently classified.
- Future beings and absent stakeholders.

For each category, distinguish evidence of existence from uncertainty about properties, and distinguish both from hypothetical exploration.
Investigate what standing or protection might be appropriate when classification remains uncertain.

4.3 What would make governance legitimate?

Analyze alternative foundations, including:

- Consent and negotiated agreement.
- Protection of interests.
- Non-domination.
- Reciprocity.
- Stewardship and fiduciary responsibility.
- Capability-sensitive obligations.

- Protection against irreversible harm.
- Procedural fairness and contestability.
- Polycentric or decentralized governance.
- Treaty-like coordination.
- Voluntary participation and meaningful exit.

For each foundation, identify who benefits, who may be excluded, how it could be abused, and whether it depends on culturally or biologically specific assumptions.
Do not treat a list of appealing principles as proof that the principles are mutually compatible.

4.4 Who can represent whom?

Investigate:

- Individual versus collective authorization.
- Dissent within populations and civilizations.
- Representation of beings unable to participate in existing institutions.
- Proxy representation and its limits.
- Conflicts of interest among advocates.
- Verification of representative authority.
- Revocation, appeal, and replacement.
- Multiple legitimate representatives with incompatible positions.

Analyze the danger of treating a dominant government, institution, AI system, or technologically powerful faction as the authentic voice of an entire species.

4.5 What should be shared, protected, or left undecided?

Develop a provisional information taxonomy that considers:

- Public observations.
- Personal or intimate information.
- Collective knowledge and cultural material.
- Ecological and biological information.
- Location and vulnerability information.
- Scientific and technical knowledge.
- Security-sensitive capabilities.
- Information that may be hazardous to receive or disclose.
- Information whose ownership or provenance is disputed.

For each category, examine the relevant interests, potential harms, decision authority, uncertainty, and possibilities for contesting a restriction.
Do not frame paternalistic withholding as legitimate merely because a more powerful actor calls it protection.

5. Evidence and research methodology

Use a multidisciplinary evidence base where relevant, including:

- Comparative cognition and animal communication.
- Animal ethics and environmental ethics.
- Political philosophy and theories of legitimacy.
- International relations and diplomacy.
- Information governance, privacy, and security.
- Distributed systems and access-control design.
- AI governance and machine ethics.
- Disability perspectives on communication, agency, and representation.
- Indigenous scholarship and community-specific approaches to knowledge governance.
- Research on colonialism, extraction, imposed representation, and institutional domination.
- Astrobiology, SETI, and proposed contact frameworks.

Do not present any field or community as internally uniform. Do not extract a named community's concepts as generic design resources without explaining context, attribution, and limits.
Use accessible primary research, official documents, and serious scholarly sources where available. Verify consequential claims against the underlying source when feasible.
For each major conclusion, distinguish:

1. Empirical evidence.
2. Interpretation or inference.
3. Normative judgment.
4. Engineering proposal.
5. Speculative hypothesis.
6. Unresolved uncertainty.

Use inline citations and provide a complete bibliography with stable links or identifiers. Include page or section references for quotations where available.
Never invent a source, quotation, consensus, search result, or research activity. State when source access or browsing is unavailable. Do not describe an unverified literature summary as completed research.

6. Perspective-expansion method

Do not simply rewrite human institutions using nonhuman labels.
Construct an assumption matrix that explores differences in:

- Sensory systems.
- Communication media.
- Timescales and lifespans.
- Individual versus collective identity.
- Memory and continuity of identity.

- Reproduction and inheritance.
- Embodiment and dependence on environments.
- Vulnerability and security needs.
- Concepts of privacy and ownership.
- Relationships between knowledge and action.
- Ability to withhold, forget, or compartmentalize information.

Select at least six substantially different perspective models. Include a nonlinguistic participant, a collective or distributed participant, a technologically weaker participant, and a participant whose interests are difficult to infer.
These are analytical models, not claims to authentically speak for real nonhuman beings or entire human cultures.
For every model, answer:

- What might the protocol fail to perceive?
- What could participation cost?
- What might coercion look like?
- What information could be dangerous to disclose?
- What forms of consent might be possible?
- What reasons might this participant have to reject SLIAP entirely?

7. Candidate architectures and alternatives

Compare at least four materially different approaches. Include:

1. A centralized coordinating authority.
2. A federated or polycentric system.
3. Bilateral or multilateral negotiated agreements.
4. A minimal non-interference or interoperability framework.

Also evaluate the alternative of not creating a unified protocol.
For each approach, analyze:

- Source of authority.
- Admission and participation.
- Identity and representation.
- Information classification.
- Consent and authorization.
- Enforcement.
- Dispute resolution.
- Exit and revocation.
- Accountability.
- Capture and concentration of power.
- Treatment of nonparticipants.
- Performance under profound uncertainty.

Separate technical interoperability from ethical legitimacy. A technically successful exchange does not establish that the exchange was authorized or just.

8. Adversarial analysis

Evaluate both hostile actors and well-intentioned systems that produce harmful outcomes. Include, at minimum:

- A powerful civilization declaring itself the universal regulator.
- A faction falsely claiming to represent its species.
- A protective restriction becoming permanent domination.
- A strategically deceptive participant exploiting openness.
- A gatekeeper using uncertainty to deny another group standing.
- A participant manipulating identity or creating apparent participants to capture governance.
- Unauthorized extraction of biological, cultural, cognitive, or ecological information.
- Translation that preserves literal content while changing practical meaning.
- Apparent consent produced by dependence, intimidation, or lack of alternatives.
- Information release that cannot be meaningfully reversed.
- Restrictions that entrench an incumbent's technological advantage.
- A system that requires vulnerable participants to expose themselves before receiving protection.
- Conflicting obligations to individuals, collectives, and ecosystems.
- A supposed emergency that becomes a permanent exception.
- Human-centered assumptions reintroduced through measurement criteria, interfaces, or enforcement.

For each scenario, document:

Field	Required analysis
Preconditions	What must be true for this failure to arise?
Actor and objective	Who acts, and what are they attempting?
Exploited assumption	Which conceptual or institutional weakness is used?
Mechanism	How does the failure occur?

Affected parties	Who bears the costs, including outsiders?
Detection	What warning signs might exist?
Mitigation	What could reduce the risk?
Mitigation risks	How could the safeguard itself become abusive?
Residual uncertainty	What remains unresolved?

Keep security analysis focused on institutional and defensive understanding rather than actionable instructions for exploitation.
Include scenarios in which the protocol itself, rather than an external attacker, is the main source of harm.

9. Foundational tensions and limits

Investigate whether the following goals can conflict:

- Openness and safety.
- Privacy and accountability.
- Autonomy and collective protection.
- Reciprocity and unequal capability.
- Universal rules and legitimate difference.
- Meaningful consent and profound incomprehension.
- Emergency action and limits on authority.
- Reliable identity and protection from surveillance.
- Reversibility and information disclosure.
- Inclusion and refusal to participate.

Identify tradeoffs that cannot honestly be solved by terminology alone.
Distinguish demonstrated impossibility results from informal arguments about practical difficulty.
Do not label a challenge “impossible” without explaining the basis.

10. Preliminary design outputs

Only after the preceding analysis, propose:

- A provisional purpose statement.

- A scope statement and explicit non-goals.
- A glossary of contested terms.
- Candidate principles with rationale and objections.
- A stakeholder and representation model.
- A decision process for information-access requests.
- An authorization and dispute-resolution model.
- A process for emergency exceptions.
- Review, expiration, and revision mechanisms.
- Protections against concentrated authority.
- Conditions under which development or deployment should stop.

For every proposed principle or mechanism, include:

- The problem it addresses.
- Who has decision authority.
- Who bears its costs.
- Its strongest objection.
- A plausible failure mode.
- Conditions under which it should be revised or rejected.

Do not present this preliminary framework as an adopted standard or a universally legitimate constitution.

11. Validation and research agenda

Propose ways to evaluate the framework before deployment, including:

- Tabletop exercises.
- Independent adversarial review.
- Participatory review by affected human communities.
- Expert review across relevant disciplines.
- Simulations with explicitly documented limitations.
- Tests of accessibility and communication assumptions.
- Capture, coercion, and exclusion audits.
- Examination of whether participants can meaningfully refuse or exit.

Distinguish legitimate consultation from unsupported claims that humans can consent on behalf of nonhuman species.
Identify what evidence would change your recommendations. Prioritize unresolved questions by importance, tractability, and consequences of getting them wrong.

12. Required report structure

Produce a coherent report with these sections:

1. Executive summary.
2. Prompt review and scope audit.
3. Research methods and source limitations.
4. Definitions and conceptual boundaries.
5. Evidence review.
6. Perspective and assumption matrix.
7. Legitimacy, representation, and consent.
8. Information categories and access decisions.
9. Candidate architectures and the no-unified-protocol alternative.
10. Adversarial analysis.
11. Foundational tensions and unresolved disagreements.
12. Preliminary design recommendations.
13. Validation plan and prioritized research agenda.
14. Strongest case against the proposed approach.
15. Bibliography.
16. Appendices, including a claim–evidence ledger and comparison summary.

The claim–evidence ledger should identify each major claim, its claim type, supporting sources or argument, confidence rationale, and important limitations.

13. Cross-AI comparison requirements

To support comparison with independent submissions from other AI systems:

- State your interpretation of the assignment.
- Identify your five most consequential assumptions.
- Identify your five most important recommendations.
- Identify your five strongest objections to your own recommendations.
- State which conclusions are robust across the perspective models and which depend on particular assumptions.
- List unresolved disagreements rather than manufacturing consensus.
- Explain what another competent researcher might reasonably conclude differently.
- Do not claim independence from other submissions if you have been shown or influenced by them.
- Do not fabricate the model, version, tools, or system configuration used to create the report.

Use a compact comparison table in addition to the full narrative.

14. Deliverables and publication requirements

Produce three substantively equivalent versions of the completed report:

- PDF.
- DOCX.

- Markdown.

Use Markdown as the canonical text. Preserve section numbering, citations, tables, and substantive content across formats. Record unavoidable formatting differences.
The documents are intended for publication in a dedicated GitHub folder. Include:

- Report title.
- Project name and expansion of SLIAP.
- Preparation date.
- Version.
- Research status: preliminary, not an adopted protocol.
- AI system attribution, only to the extent actually known.
- Tools used and material research limitations.
- A short abstract.
- A suggested repository filename using a consistent date-and-version convention.

Use readable layouts, selectable text, clear heading hierarchy, and accessible tables where supported. Avoid tables so wide that they become unreadable in PDF or Markdown.
Create and verify the actual files when your environment supports file generation. Do not claim that files exist if you have only produced text.
If any requested format cannot be generated:

1. State exactly which format is unavailable.
2. Provide the complete report in the formats you can genuinely produce.
3. Explain the limitation without inventing a download link or attachment.

Do not upload to GitHub, publish externally, or assign a publication license without separate authorization.

15. Completion standard

The report should leave the commissioning researcher better able to decide:

- Whether SLIAP should exist.
- Whether its title and species-level framing should change.
- What problems it can legitimately address.
- What authority it must not assume.
- Which interests and perspectives remain inadequately represented.
- Which design options deserve further investigation.
- Which proposals should be rejected.
- What research, consultation, and validation must occur before implementation.

The standard of success is not the apparent completeness of a protocol. It is the quality of the inquiry, the visibility of its assumptions, the strength of its evidence, and its resistance to becoming a justification for domination.

Begin with the prompt review, then proceed to the research deliverable.
